Abstract

We study the exclusive production of $J^{PC} = 0^{++}, 0^{-+}$ charmonium states in proton-proton collisions at the LHC energies. The $pp \rightarrow pp\eta_c$ reaction is discussed for the first time. We observe a substantial contribution from the nonperturbative domain of gluon virtualities, especially for η_c production. To model the nonperturbative region better, we utilize models of the unintegrated gluon distribution based on parametrizations of the color dipole cross-section.

1 Introduction

Central exclusive diffractive processes are distinguished by their very unusual final states. The diffractively excited system, e.g. a meson or a few-particle state is produced in the central rapidity region and is fully measured. There are no other tracks in the detectors, except perhaps the tagged final state protons. Beyond the fully exclusive or “elastic” diffraction where the incoming protons remain intact, in absence of proton tagging also “inelastic diffraction” must be accounted for, where small mass hadronic systems, disappear into the beam pipe. Here we give a brief summary of our recent work [1] where we have considered two such reactions, $pp \rightarrow p\chi_{c0}p$ and $pp \rightarrow p\eta_c p$. The final state mesons being composed of heavy (charm) quarks, these processes appear to be well suited to be analysed in the framework of the perturbative QCD (pQCD) based on the “Durham model” formulated by Khoze, Martin and Ryskin (see Ref. [2] and references therein). Building upon the Durham formulation, the theory of the central exclusive production (CEP) of single χ_{cJ} , $J = 0, 1, 2$ mesons, with a correct account for the spin of the mesons and precise kinematics of the process has been worked out by Pasechnik, Szczurek and Teryaev (PST) in a series of papers [3–5]. Here we review our recent work,

where we revisited and extended this analysis to account for additional effects and sources for theoretical uncertainties (such as the shapes of the charmonia wave functions). Also, for the first time, we studied the pseudoscalar η_c final state.

2 Formalism and Results

2.1 pQCD description of central exclusive diffraction

For the production of bound states of heavy quarks, the quark mass provides a hard scale, and one may attempt a pQCD formulation of the CEP process. The Durham group have proposed a factorization of the CEP amplitude indicated graphically in Fig. 1 – for a review, see [2]. The

Figure 1: A Feynman diagram for the CEP process.

production of the quarkonium proceeds through the fusion of two gluons. Another gluon – the so-called screening gluon – is exchanged between protons and ensures that the t -channel exchange is in the color-singlet. The factorization formula for the CEP amplitude reads:

$$\mathcal{M} = \frac{is}{4\pi^2} \frac{\delta_{c_1 c_2}}{N_c^2 - 1} \int d^2\mathbf{Q} \mathcal{V}^{c_1 c_2}(\mathbf{q}_1, \mathbf{q}_2) \frac{\mathcal{F}_g^{\text{off}}(x_1, x', \mathbf{Q}^2, \mathbf{q}_1^2, \mu^2, t_1) \mathcal{F}_g^{\text{off}}(x_2, x', \mathbf{Q}^2, \mathbf{q}_2^2, \mu^2, t_2)}{\mathbf{Q}^2 \mathbf{q}_1^2 \mathbf{q}_2^2}, \quad (1)$$

where $\mathcal{V}^{c_1 c_2}(\mathbf{q}_1, \mathbf{q}_2)$ is the vertex that describes the $g^* g^* \rightarrow \chi_c$ or $g^* g^* \rightarrow \eta_c$ transitions. It is contracted with the polarization vectors of off-shell gluons which are represented by the light-like vectors n_μ^\pm :

$$n_\mu^+ n_\nu^- \mathcal{V}^{ab}(\mathbf{q}_1, \mathbf{q}_2) = \frac{4\pi\alpha_s}{\sqrt{N_c}} \delta^{ab} \mathcal{T}. \quad (2)$$

For the case of the χ_{c0} , the transition amplitude can be decomposed into two form-factors

$$\mathcal{T} = |\mathbf{q}_1||\mathbf{q}_2| G_1(\mathbf{q}_1^2, \mathbf{q}_2^2) + (\mathbf{q}_1 \cdot \mathbf{q}_2) G_2(\mathbf{q}_1^2, \mathbf{q}_2^2), \quad (3)$$

for which we have derived a representation in terms of light-front wave functions (LFWFs) [7]:

$$\begin{aligned} G_1(\mathbf{q}_1^2, \mathbf{q}_2^2) &= |\mathbf{q}_1||\mathbf{q}_2| \frac{4m_c}{\mathbf{q}_2^2} \int \frac{dz d^2\mathbf{k}}{z(1-z)16\pi^3} \psi_{\chi_{c0}}(z, \mathbf{k}) 2z(1-z)(2z-1) \left[\frac{1}{l_A^2 + \varepsilon^2} - \frac{1}{l_B^2 + \varepsilon^2} \right] \\ G_2(\mathbf{q}_1^2, \mathbf{q}_2^2) &= 4m_c \int \frac{dz d^2\mathbf{k}}{z(1-z)16\pi^3} \psi_{\chi_{c0}}(z, \mathbf{k}) \left[\frac{1-z}{l_A^2 + \varepsilon^2} + \frac{z}{l_B^2 + \varepsilon^2} \right] \\ &+ \frac{4m_c}{\mathbf{q}_2^2} \int \frac{dz d^2\mathbf{k}}{z(1-z)16\pi^3} \psi_{\chi_{c0}}(z, \mathbf{k}) 4z(1-z) \left[\frac{\mathbf{q}_2 \cdot \mathbf{l}_A}{l_A^2 + \varepsilon^2} - \frac{\mathbf{q}_2 \cdot \mathbf{l}_B}{l_B^2 + \varepsilon^2} \right], \end{aligned} \quad (4)$$

with $\mathbf{l}_A = \mathbf{k} - (1-z)\mathbf{q}_2$, $\mathbf{l}_B = \mathbf{k} + z\mathbf{q}_2$ and $\varepsilon^2 = m_c^2 + z(1-z)\mathbf{q}_1^2$. The LFWFs are obtained using the well-known Terent'ev prescription from potential model rest frame wave functions.

For the case of the pseudoscalar η_c , there is only one form factor,

$$\mathcal{T} = (-i)[\mathbf{q}_1, \mathbf{q}_2]I(\mathbf{q}_1^2, \mathbf{q}_2^2), \quad (5)$$

which reads [6]:

$$I(\mathbf{q}_1^2, \mathbf{q}_2^2) = 4m_c \int \frac{dz d^2\mathbf{k}}{z(1-z)16\pi^3} \psi_{\eta_c}(z, \mathbf{k}) \left\{ \frac{1-z}{l_A^2 + \varepsilon^2} + \frac{z}{l_B^2 + \varepsilon^2} \right\}.$$

$$\mathcal{F}_{g,\text{KMR}}^{\text{off}}(x, x', \mathbf{Q}^2, \mathbf{q}^2, \mu^2, t) = R_g \frac{d}{d \ln \mathbf{q}^2} \left[x g(x, \mathbf{q}^2) \sqrt{T_g(\mathbf{q}^2, \mu^2)} \right]_{\mathbf{q}^2 = \mathbf{Q}^2} \cdot F(t). \quad (6)$$

The coupling of gluons to protons is described by a generalized unintegrated gluon distribution (UGD). Here several prescriptions exist in the literature:

$$\mathcal{F}_{g,\text{CDHI}}^{\text{off}}(x, x', \mathbf{Q}^2, \mathbf{q}^2, \mu^2, t) = R_g \left[\frac{\partial}{\partial \log \bar{\mathbf{Q}}^2} \sqrt{T_g(\bar{\mathbf{Q}}^2, \mu^2)} x g(x, \bar{\mathbf{Q}}^2) \right] \cdot \frac{2\mathbf{Q}^2 \mathbf{q}^2}{\mathbf{Q}^4 + \mathbf{q}^4} \cdot F(t), \quad (7)$$

with $\bar{\mathbf{Q}}^2 = (\mathbf{Q}^2 + \mathbf{q}^2)/2$, or

$$\mathcal{F}_{g,\text{PST}}^{\text{off}}(x, x', \mathbf{Q}^2, \mathbf{q}^2, \mu^2, t_i) = \sqrt{\mathbf{Q}^2 f_g^{\text{GBW}}(x', \mathbf{Q}^2) \mathbf{q}^2 f_g^{\text{GBW}}(x, \mathbf{q}^2)} \sqrt{T_g(\mathbf{q}^2, \mu^2)} \cdot F(t), \quad (8)$$

for more details, see [7]. The factor R_g takes into account the so-called skewedness correction, which comes from the fact, that the screening gluon carries a much smaller x than the fusing gluons. In Fig. 2 we show rapidity and transverse momentum dependent cross sections for η_c and χ_{c0} CEP for different prescriptions and choices of gluon distributions. In Fig. 3 distributions in Mandelstam- t_1, t_2 are shown. We observe the forward dip for η_c and peak for χ_{c0} at small $t_{1,2}$.

2.2 Absorptive corrections

The results shown up to now do not contain the gap survival factors, which encode the effect of absorptive corrections. We estimate the latter in an admittedly crude elastic rescattering approximation. The full amplitude is written as

$$\mathcal{M}(Y, y, \mathbf{p}_1, \mathbf{p}_2) = \mathcal{M}^{(0)}(Y, y, \mathbf{p}_1, \mathbf{p}_2) - \delta \mathcal{M}(Y, y, \mathbf{p}_1, \mathbf{p}_2), \quad (9)$$

with the Born amplitude described above, and the absorptive correction being:

$$\begin{aligned} \delta \mathcal{M}(Y, 0, \mathbf{p}_1, \mathbf{p}_2) &= \int \frac{d^2\mathbf{k}}{2(2\pi)^2} T(s, \mathbf{k}) \exp\left(-\frac{1}{2}B_D(\mathbf{p}_1 + \mathbf{k})^2\right) \exp\left(-\frac{1}{2}B_D(\mathbf{p}_2 - \mathbf{k})^2\right) \\ &\times V(\mathbf{p}_1 + \mathbf{k}, \mathbf{p}_2 - \mathbf{k}), \end{aligned} \quad (10)$$

with an effective vertex V that describes the fusion of two Pomerons into the meson. It is adjusted to the Born results of the previous sections together with parameter B_D . Above,

$$T(s, \mathbf{k}) = \sigma_{\text{tot}}^{pp}(s) \exp\left(-\frac{1}{2}B_{\text{el}}(s)\mathbf{k}^2\right), \quad (11)$$

is the elastic pp amplitude. We show the gap survival factor

$$S^2 \equiv \frac{d\sigma/dy \Big|_{y=0}}{d\sigma_{\text{Born}}/dy \Big|_{y=0}}. \quad (12)$$

in Table 1 for χ_{c0} and in Table 2 for η_c .

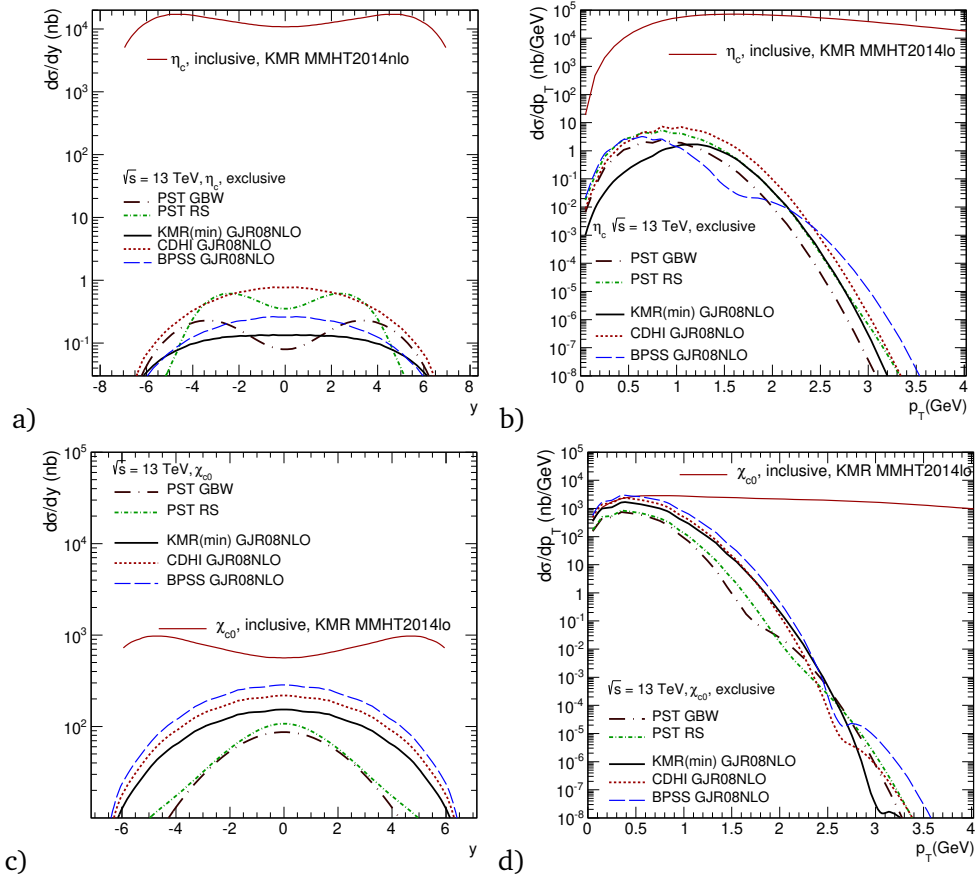

Figure 2: a) Rapidity dependent cross section and b) transverse momentum dependent cross section for η_c CEP for various UGD prescriptions; c) & d): the analogous cross sections for χ_{c0} CEP. Also shown are the cross sections for the relevant inclusive (nondiffractive) cross section.

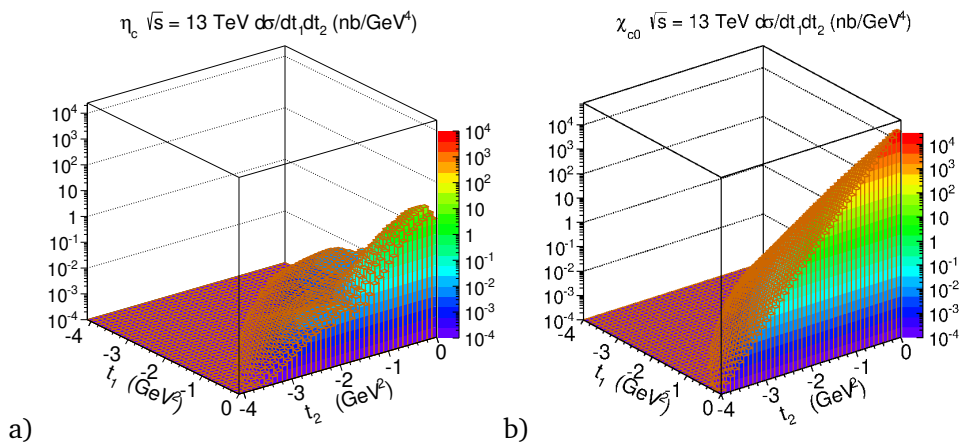

Figure 3: Cross section for a) η_c and b) χ_{c0} CEP differential in Mandelstam- t_1, t_2 . Here we used the PST prescription.

3 Conclusion

We have revisited the pQCD formulation of CEP in the example of the production of spinless quarkonia [1]. The case of the pseudoscalar η_c was calculated for the first time. The novelty consists of the treatment of the transition amplitude for $g^*g^* \rightarrow \eta_c$ and $g^*g^* \rightarrow \chi_{c0}$ which was calculated [6, 7] using the light-cone wave functions of $c\bar{c}$ states in the framework of potential models. It turns out that the CEP processes in proton-proton collisions studied by us are sensitive to rather low momentum scales. This is the case especially for the η_c , and is responsible for the main uncertainties in the results. We consequently proposed a way to calculate the soft effects (in the region of small gluon transverse momenta) using UGDs obtained from color dipole models and a simple (PST) prescription for its off-diagonal extrapolation. In our treatment of absorptive corrections, we restricted ourselves to the so-called elastic rescattering correction. Depending on the UGD used, we obtain for the χ_c the gap survival values of $S^2 = (0.13-0.21)$, while for the η_c production, they are somewhat higher, $S^2 = (0.21-0.38)$.
