Abstract

The searches for additional Higgs bosons decaying to tau leptons in scenarios beyond the standard model will be summarised, from the pp collision data collected by the ATLAS and CMS experiments at LHC Run-2.

1 Introduction

The discovery of a new particle in July 2012 by the ATLAS \(^1\) and CMS \(^2\) collaborations at the Large Hadron Collider (LHC) \(^3\) \(^4\) \(^5\), compatible with the standard model (SM) Higgs boson, is a fundamental step forward in our understanding of the electroweak spontaneous symmetry breaking. However, many open questions, including the problem
of the large hierarchy between the Planck and electroweak scale, still need to be addressed.

In order to cope with this, many different extension of the SM have been proposed, like
supersymmetry (SUSY) \[6,7\].

Extending the SM entails, in most of the cases, the extension of the Higgs sector. One
of the simple extensions is described by the 2 Higgs Doublet Model (2HDM), where two
scalar Higgs doublets are introduced. The spontaneous symmetry breaking give rise to
five scalar bosons: a neutral CP-odd $A$, two neutral CP-even $h$ and $H$, two charged bosons
$H^\pm$. In the decoupling limit, the lightest scalar of 2HDM can have properties compatible
with the discovered Higgs boson; in this scenario all other scalars have larger masses.

Considering how the two doublets can interact with other particles of the SM, different
phenomenology scenarios can appear. One of this scenarios is the Type-II 2HDM, which
supposes that the first doublet couples only with up-quarks, while the second doublet only
with down-quarks and charged fermions.

The Minimal Supersymmetric Standard Model (MSSM) \[8,9\], which incorporate the
supersymmetry, is a Type-II 2HDM. At tree level, all the phenomenology can be described
by two parameters, conventionally chosen to be the mass of the pseudoscalar Higgs $m_A$
and the ratio between the two vacuum expectation values (VEVs) $\tan\beta = \nu_1/\nu_2$.

For $A$ and $H$ the dominant production process is still the gluon fusion, for small and
medium values of $\tan\beta$, followed by the $b\bar{b}$-associated production, that increase at high
$\tan\beta$ due to the second doublet couplings to down-type fermions. The $H^\pm$ production
mechanism is strictly connected to the mass of the charged boson. For masses below the
top-quark mass ($m_{H^\pm} < m_t$) the decay mode in a $\tau$ lepton plus neutrino dominate in a
Type-II 2HDM scenario; for mass above the top-quark mass ($m_{H^\pm} > m_t$), decay mode $\tau\nu$
increase with $\tan\beta$. In this report, results of direct searches of MSSM Higgs bosons with
tau leptons in the final state, from the ATLAS and CMS collaborations using the 2016
dataset, are presented.

A complex $SU(2)_L$ singlet field $S$ can be added to 2HDM, with a small mixing with
the doublets; such a model is called 2HDM+S. This leads to two additional singlet states,
a CP-odd scalar $a$ and a CP-even $s$, which inherit a mixture of the Higgs doublets fermion
interactions. In such a model, also known as NMSSM, the branching fraction of the Higgs
boson to a pair of $a$ or $s$ bosons can be sizeable, and a wide variety of exotic Higgs decays
are allowed \[10\], especially $h \rightarrow aa$. In this report, results of direct searches of $h \rightarrow aa$
with tau leptons in the final state, from the CMS collaborations using the 2016 dataset,
are presented.

2 Search for a neutral MSSM Higgs boson decaying into $\tau\tau$

The coupling of the $H$ and the $A$ to down-type fermions, at leading-order (LO), is en-
hanced by $\tan\beta$ with respect to the expectation for an SM Higgs boson of the same mass,
while the coupling to vector bosons and up-type fermions is suppressed. The enhanced
coupling to down-type fermions makes searches for additional heavy neutral Higgs bosons
that exploit final states containing $\tau\tau$ particularly interesting. It also has consequences
for the production: firstly, the production in association with $b$ quarks dominates over
the production via gluon fusion for large values of $\tan\beta$. Secondly, in gluon fusion pro-
duction the kinematic properties of the Higgs boson change as a function of $\tan\beta$ due to
the increasing contribution of $b$ quarks in the fermion loop. Diagrams for $h$, $H$, and $A$
production at LO are shown in Figure 1.

The ATLAS and CMS collaborations performed the direct search in the most sensitive
final states of the taus \[11,12\]. Both focus their attention on $e\tau_h$, $\mu\tau_h$ and $\tau_h\tau_h$, where $\tau_h$
Figure 1: Feynman diagrams of the production modes of an neutral MSSM Higgs boson. (top) Gluon gluon fusion; (bottom-left) bb-associated production four-flavour scheme; (bottom-right) bb-associated production five-flavour scheme

Figure 2 shows the upper limits obtained by the ATLAS and CMS collaborations as a function of Higgs boson mass.

Results are re-interpreted in two different benchmark scenario models; the $m_{h}^{\text{mod+}}$ and the hMSSM scenarios [13,14]. Figure 3 shows limits set on $m_A - \tan \beta$ plane.
Figure 2: (top) CMS expected and observed limits on $\sigma(\phi) \times BR(\phi \to \tau\tau)$ for (left) the gluon fusion and (right) the $b\bar{b}$-associated production, resulting from the combination of all the four channels considered. (bottom) ATLAS expected and observed limits on $\sigma(\phi) \times BR(\phi \to \tau\tau)$ for (left) the gluon fusion and (right) the $b\bar{b}$-associated production, resulting from the combination of all the three channels considered. [11] [12]
Figure 3: Model dependent exclusion limits in the $m_A - \tan \beta$ plane for the (left) $m_{h^\text{mod}+}^\text{mSUSY}$ and the (right) hMSSM scenarios. In the top left plot, the red shade area indicates the region that does not give a light $h$ higgs boson consistent with a mass of 125 GeV within the theoretical uncertainties ±3 GeV. In the bottom left plot, the red dashed lines represent the different parameters value that give a particular $m_h$ value. In the bottom right plot, the purple area indicates the region already excluded by constrains on $h(125)$ couplings. [11] [12]
3 Search for charged Higgs bosons with the $H^\pm \rightarrow \tau^\pm \nu$

The $H^\pm$ production mechanism is strictly connected to the mass of the charged boson. If the $H^\pm$ mass is below the top-quark mass ($m_{H^\pm} < m_t$), the production mode goes through the decay of a top-quark, $t \rightarrow bH^+$, in a $t\bar{t}$ production. In this mass range, the decay mode in a $\tau$ lepton plus a neutrino dominate in a Type-II 2HDM scenario. If the $H^\pm$ mass above the top-quark mass ($m_{H^\pm} > m_t$), the dominant production mode is $gg \rightarrow tbH^+$. In this mass range, the dominant decay is $H^+ \rightarrow tb$, considering the alignment limit ($\cos \beta - \alpha \simeq 0$) \cite{15}; however the branching fraction for $H^+ \rightarrow \tau \nu$ can reach up to $10^{-15}$% at high $\tan \beta$. The mass region where the $H^\pm$ and the top-quark masses are similar ($m_{H^\pm} \simeq m_t$) involves interference effects among the $t\bar{t}$ and $H^\pm$ non-resonant top-quark productions. Recently theoretical prediction become available for this region \cite{16}, which now allows to compare directly the $H^\pm$ model with data in proximity of the top-quark mass. In Figure 4 the different production modes Feynman diagrams are depicted.

![Feynman Diagrams](image)

**Figure 4:** Examples of leading-order Feynman diagrams contributing to the production of charged Higgs bosons in pp collisions: (left) non-resonant top-quark production, (center) single-resonant top-quark production that dominates at large $H^+$ masses, (right) double-resonant top-quark production that dominates at low $H^+$ masses. The interference between these three main diagrams becomes most relevant in the intermediate-mass region.

The ATLAS and CMS collaboration searched for a charged Higgs boson in pp collision using a dataset corresponding to an integrated luminosity of $\sim 36 fb^{-1}$, at a center-of-mass energy of 13 TeV \cite{17} \cite{18}. The results presented will refer to the ATLAS search, the only one with the full 2016 dataset public at the time of the conference.

Two different channels are considered: $\tau_h$+jets and $\tau_h$+lepton, where both aim to different decays of the top-quark produced with the $H^\pm$. Furthermore, a multivariate discriminant is used to increase the search sensitivity, exploiting the kinematic variables that differentiate between signal and backgrounds. The output score of a Boosted Decision Trees (BDTs) is used as final discriminant. In order to take advantage of the different $H^\pm$ decay products’ kinematic regime, simulated signal sample are divide in five $H^\pm$ mass bins: 90–120 GeV, 130–160 GeV, 160–180 GeV, 200–400 GeV and 500–2000 GeV. The BDTs are trained using a set of variables related to the particular final state.

Backgrounds classification and estimation depends on the type of object that gives rise to the identified $\tau_h$. If $\tau_h$ arise from a true hadronically decaying tau or electron/muon misidentification, simulation is used to estimate such backgrounds like $Z$+jets, $W$+jets or dibosons; however, in the case of $t\bar{t}$ events, the normalization is obtained from a fit to the data. If $\tau_h$ arise from a misidentified gluon-jet or quark-jet, the Fake Factor Method is used to estimate such background \cite{17}. Figure 5 shows the BDTs output for the $\tau_h$+jets final state after estimating the different background contributions.
BDTs binned distribution are fitted simultaneously in all the three signal regions. The data are found to be consistent with the background-only hypothesis. Exclusion limits are set at 95% CL on $\sigma(pp \to tbH^+) \times B(H^+ \to \tau\nu)$ for the full mass range, as well as on $B(t \to bH^+) \times B(H^+ \to \tau\nu)$ for low mass range. Figure 5 shows the expected and observed exclusion limits as a function of the $H^\pm$ mass hypothesis. Figure 6 shows 95% CL exclusion limits on tan$\beta$ as a function of the charged Higgs boson mass in the context of the hMSSM scenario.

Figure 5: BDTs score distributions in the signal region of the $\tau_h+\text{jets}$ channel, in the five mass ranges used for the BDTs trainings, after a fit to the data with the background-only hypothesis. The lower panel of each plot shows the ratio of data to the SM background prediction. The uncertainty bands include all statistical and systematic uncertainties. The normalisation of the signal (shown for illustration) corresponds to the integral of the background. [17]
Figure 6: Observed and expected 95% CL on (left) $\sigma(pp \to tbH^+) \times B(H^+ \to \tau\nu)$ and (right) $B(t \to bH^+) \times B(H^+ \to \tau\nu)$ as a function of the charged Higgs boson mass, after combining the $\tau_h$+jets and $\tau_h$+leptons channels. [17]

Figure 7: 95% CL exclusion limits on $\tan\beta$ as a function of the charged Higgs boson mass in the context of the hMSSM scenario, for the regions in which theoretical predictions are available ($0.5 \leq \tan\beta \leq 60$). [17]
4 Search for new light bosons in decays of the $h(125)$

The combination of data collected at center-of-mass energies of 7 and 8 TeV by ATLAS and CMS constrains branching fractions of the Higgs boson to particles beyond the SM to less than 34% at 95% CL [19]. Decay chains $h(125) \rightarrow aa$ are allowed in 2HDM+S scenarios.

Among all the possible 2HDM+S scenarios, only four type forbid flavour-changing neutral current at tree level. In Type-I, all SM particles couple to the first doublet. In Type-II, up-type quarks couple to the first doublet, whereas leptons and down-type quarks couple to the second doublet. NMSSM is a particular case of 2HDM+S of Type-II. In Type-III, quarks couple to the first doublet, and leptons to the second one. Finally, in Type-IV, leptons and up-type quarks couple to the first doublet, while down-type quarks couple to the second doublet.

The analysis presented here are based on pp collisions collected in 2016 by the CMS experiment at a center-of-mass energy of 13 TeV, corresponding to an integrated luminosity of $35.9 fb^{-1}$. Decay chains considered are $aa \rightarrow b\bar{b}\tau\bar{\tau}$ [20] and $aa \rightarrow \mu\mu\tau\tau$ [21]. Masses of the pseudoscalar boson between 15.0 and 62.5 GeV are probed.

4.1 $h \rightarrow aa \rightarrow b\bar{b}\tau\bar{\tau}$

Three different $\tau\tau$ final states are considered: $e\mu$, $e\tau_h$, and $\mu\tau_h$. They are additionally required to contain at least one b-tagged jet.

To increase the sensitivity of the analysis, events in each final state are separated into four categories with different signal-to-background ratios. The categories are defined on the basis of $m_{\tau\tau b}$, the invariant mass of the visible decay products of the $\tau$ leptons and the b-tagged jet with the highest $p_T$. This variable exploits the difference in the kinematics of the final objects in signal events and background events. Usually, $m_{\tau\tau b}$ has low values for the former and high for latter.

The dominant backgrounds, having these objects in the final state, are $t\bar{t}$ and $Z \rightarrow \tau\tau$ production. Another large background consists of events with jets misidentified as $\tau_h$, such as $W+$jets events, the background from SM events composed uniquely of jets produced through the strong interaction, referred to as QCD multijet events, or semileptonic $tt$ events. The misidentified background is estimated through the Fake Rate Method described in [20].

4.2 $h \rightarrow aa \rightarrow \mu\mu\tau\tau$

The analysis focus on four different final states that cover the different possible $\tau$ lepton decay modes: $\mu\mu + e\mu$, $\mu\mu + e\tau_h$, $\mu\mu + \mu\tau_h$, and $\mu\mu + \tau_h\tau_h$. The $\mu\mu + ee$ and $\mu\mu + \mu\mu$ final states are not considered because of their smaller branching fractions and the large background contribution from $ZZ$ production.

The background composed of events where at least one jet is misidentified as one of the final state leptons is estimated from data. Such events include mostly $Z+$jets and $WZ+$jets events, but there are also minor contributions from $ZZ \rightarrow 2l2q$ events, $t\bar{t}$ production, or from the background from SM QCD multijet events.

The analysis scans the reconstructed dimuon mass spectrum for a characteristic resonance structure. The event selection and signal extraction used in this analysis are optimized for the $h \rightarrow aa \rightarrow \mu\mu\tau\tau$ decay channel, where $h$ has a mass of 125 GeV. Events from the $h \rightarrow aa \rightarrow \tau\tau\tau\tau$ process can also enter the signal region when at least two of the $\tau$ leptons decay leptonically to muons and neutrinos. These events are treated as a part of the signal even if they do not exhibit a narrow dimuon mass peak.
4.3 Results

For the $h \rightarrow aa \rightarrow bb\tau\tau$ decay channel, a global binned maximum-likelihood fit based on the $m_{\tau\tau}^a$ distributions, in the different channels and categories, is performed for the search for an excess of signal events over the expected background. Unbinned maximum-likelihood fit to the dimuon invariant mass distribution is used in the $h \rightarrow aa \rightarrow \mu\mu\tau\tau$ decay channel.

No significant excess of data is observed above the expected SM background. Upper limits at 95% CL are set on $(\sigma(h)/\sigma_{SM}) \times B(h \rightarrow aa \rightarrow bb\tau\tau)$ for pseudoscalar masses between 15.0 and 62.5 GeV.

Figure 8 shows 95% CL upper limits obtained from combining the different final states considered in each analysis.

This translates to limits on $(\sigma(h)/\sigma_{SM}) \times B(h \rightarrow aa)$ in the different 2HDM+S scenarios. As explained at the beginning of Section 4.2, the different scenarios are related to how the leptons, up-quark, and down-quark interact with the two doublets introduced. The two analyses have different sensitivity in the $m_a - \tan \beta$ plane due to the involvement of down-quarks and leptons in the $bb\tau\tau$ and only leptons in $\mu\mu\tau\tau$. In the Type-I scenario, and Type-II scenario, with $\tan \beta > 1$, assuming the SM production cross section and mechanisms for the Higgs boson, limits on $(\sigma(h)/\sigma_{SM}) \times B(h \rightarrow aa)$ are reduced to 20% for $bb\tau\tau$ and down to 33% for $\mu\mu\tau\tau$. For Type-III and Type-IV scenarios, the limits are depicted in Figure 9.

5 Conclusion

Several searches for BSM Higgs bosons, with tau leptons in the final state, have been carried out in the ATLAS and CMS experiments using 2015+2016 data at $\sqrt{s} = 13$ TeV. No evidence of additional Higgs bosons has been observed. Upper limits are provided on the cross-section times branching fraction for different searches. The results are, furthermore, interpreted in the context of an extended Higgs sector, such as MSSM and NMSSM. The full Run-2 data, in which the integrated luminosity has reached $\sim 140 fb^{-1}$ will give an incredible boost to the sensitivity for searches of new physics in the Higgs sector.
Figure 9: Observed 95% CL limits on \( \left( \sigma(h)/\sigma_{SM} \right) \times B(h \to aa) \) in 2HDM+S of type III (left), and type IV (right). The contours corresponding to a 95% CL exclusion of \( \left( \sigma(h)/\sigma_{SM} \right) \times B(h \to aa) = 1.00 \) and 0.34 are drawn with dashed lines. The number 34% corresponds to the limit on the branching fraction of the Higgs boson to beyond-the-SM particles at the 95% CL obtained with data collected at center-of-mass energies of 7 and 8 TeV by the ATLAS and CMS experiments [19, 20, 21].
