Abstract

Rapidly rotating Myers-Perry-AdS black holes are unstable against rotational superradiance. From the onset of the instability, cohomogeneity-1 black resonators are constructed in five-dimensional asymptotically AdS space. By using the cohomogeneity-1 metric, perturbations of the cohomogeneity-1 black resonators are also studied.

11 1 Introduction

12 In asymptotically AdS space, rotational gravitational superradiance leads to superradiant insta-
13 bility to rotating AdS black holes [1, 2]. From the onset of the instability, solutions called black
14 resonators branches off [3]. They are connected to geons in the limit of the zero horizon size.
15 These solutions are characterized by having a helical Killing vector, where the time and rota-
16 tion translations of the rotating black hole are broken to a helical one. Black resonators hence

17 have less isometries than the stationary rotating black holes. Indeed, they are non-stationary
 18 solutions. Black resonators and geons were first constructed in four dimensions [3], where the
 19 helical Killing vector is the only continuous symmetry. Recently, by going to five dimensions
 20 and exploiting the extra symmetries in the case of equal angular momenta, black resonators
 21 and geons with cohomogeneity-1 metric have been constructed [4]. Solutions coupled to elec-
 22 tromagnetic waves have also been obtained [5]. By making use of the cohomogeneity-1 met-
 23 ric, perturbations of the black resonators have been studied in [6]. A similar five-dimensional
 24 cohomogeneity-1 resonating AdS soliton geometry was also found [7].

25 2 Cohomogeneity-1 black resonators and geons

26 Cohomogeneity-1 black resonators and geons are obtained in Einstein gravity in asymptotically
 27 global AdS space in five dimensions [4]. The metric ansatz is

$$ds^2 = -(1+r^2)f(r)d\tau^2 + \frac{dr^2}{(1+r^2)g(r)} + \frac{r^2}{4} \left[\alpha(r)\sigma_1^2 + \frac{1}{\alpha(r)}\sigma_2^2 + \beta(r)(\sigma_3 + 2h(r)d\tau)^2 \right], \quad (1)$$

28 where σ_a ($a = 1, 2, 3$) are one-forms given by

$$\begin{aligned} \sigma_1 &= -\sin\chi d\theta + \cos\chi \sin\theta d\phi, \\ \sigma_2 &= \cos\chi d\theta + \sin\chi \sin\theta d\phi, \\ \sigma_3 &= d\chi + \cos\theta d\phi. \end{aligned} \quad (2)$$

29 The angular coordinates (θ, ϕ, χ) are defined in $0 \leq \theta < \pi$, $0 \leq \phi < 2\pi$, and $0 \leq \chi < 4\pi$.
 30 The range of the radial coordinate r is from either the origin $r = 0$ (for geons) or some horizon
 31 radius $r = r_h$ (for black holes) to asymptotic infinity $r \rightarrow \infty$. The metric is assumed to be
 32 asymptotically AdS₅ in $r \rightarrow \infty$ where h approaches a constant and $f, g, \alpha, \beta \rightarrow 1$.

33 The Myers-Perry AdS black hole with equal angular momenta is a solution to the Einstein
 34 equations within the metric ansatz (1). It is given by

$$\begin{aligned} g(r) &= 1 - \frac{2\mu(1-a^2)}{r^2(1+r^2)} + \frac{2a^2\mu}{r^4(1+r^2)}, & \beta(r) &= 1 + \frac{2a^2\mu}{r^4}, \\ h(r) &= \Omega - \frac{2\mu a}{r^4 + 2a^2\mu}, & f(r) &= \frac{g(r)}{\beta(r)}, & \alpha(r) &= 1, \end{aligned} \quad (3)$$

35 where the angular velocity Ω is

$$\Omega = \frac{2\mu a}{r_h^4 + 2a^2\mu}. \quad (4)$$

36 The horizon radius r_h is given by the largest real root of $g(r_h) = 0$. The isometry group of
 37 a general Myers-Perry black hole with independent rotations is $\mathbb{R} \times U(1) \times U(1)$, where \mathbb{R}
 38 is the time translation and the $U(1)$ are for the rotations. When the two angular momenta are
 39 equal, it is enhanced to $\mathbb{R} \times U(2)$. There are $SU(2)$ angular momentum operators L_i satisfying
 40 $[L_i, L_j] = i\epsilon_{ijk}L_k$, and each 1-form σ_a is invariant under the $SU(2)$: $L_i\sigma_a \equiv \mathcal{L}_{L_i}\sigma_a = 0$, where
 41 \mathcal{L}_{L_i} denotes the Lie derivative. The $U(1) \subset U(2)$ is generated by a shift of χ : $R_z \equiv i\partial_\chi$.

42 This Myers-Perry AdS black hole has a gravitational superradiant instability that breaks the
 43 $U(1)$ isometry. Here we focus on a τ -independent linear perturbation of the form

$$\delta g_{\mu\nu} dx^\mu dx^\nu = \frac{r^2}{4} \delta\alpha(r)(\sigma_1^2 - \sigma_2^2) = \frac{r^2}{2} \delta\alpha(r)(\sigma_+^2 + \sigma_-^2), \quad (5)$$

44 where we defined

$$\sigma_{\pm} = \frac{1}{2}(\sigma_1 \mp i\sigma_2) = \frac{1}{2}e^{\mp i\chi}(\mp id\theta + \sin\theta d\phi). \quad (6)$$

45 This perturbation is $SU(2)$ -invariant, but the terms with σ_{\pm}^2 have the $U(1)$ -charges ± 2 , respec-
 46 tively, and hence it is not invariant under the $U(1)$ shift of $\chi: \chi \rightarrow \chi + \text{const}$. This perturbation
 47 results in a decoupled perturbation equation for $\delta\alpha$,

$$\delta\alpha'' + \left(\frac{g'}{g} + \frac{3+5r^2}{r(1+r^2)}\right)\delta\alpha' + \frac{8}{(1+r^2)g} \left(\frac{\beta-2}{r^2\beta} + \frac{2\beta h^2}{(1+r^2)g}\right)\delta\alpha = 0, \quad (7)$$

48 where g and β are given in (3). For fixed r_h , this equation can be solved by a nontrivial normal
 49 modes $\delta\alpha$ at a critical value of Ω that corresponds to the onset of the superradiant instability.
 50 The Myers-Perry black hole with equal angular momenta is unstable above that frequency, and
 51 the $U(1)$ isometry is broken when this instability turns up.

52 From the superradiant instability, black resonators with $R \times SU(2)$ isometries branch off.
 53 The Einstein equations under the metric ansatz (1) can be solved for $\alpha(r) \neq 1$, and such
 54 solutions are no longer invariant under the $U(1)$. To solve the Einstein equations for black
 55 resonators, we take $h = 0$ at the horizon and require $f, g, \alpha, \beta \rightarrow 1$ and $h \rightarrow \Omega$ in $r \rightarrow \infty$.
 56 These boundary conditions correspond to the rotating frame at infinity, for which we use (τ, χ) .
 57 We can switch to the non-rotating frame at infinity (t, ψ) by

$$dt = d\tau, \quad d\psi = d\chi + 2\Omega d\tau. \quad (8)$$

58 In the non-rotating frame, periodic time dependence explicitly appears in the metric as

$$\alpha\sigma_1^2 + \frac{1}{\alpha}\sigma_2^2 = 2\left(\alpha + \frac{1}{\alpha}\right)\bar{\sigma}_+\bar{\sigma}_- + \left(\alpha - \frac{1}{\alpha}\right)(e^{4i\Omega t}\bar{\sigma}_+^2 + e^{-4i\Omega t}\bar{\sigma}_-^2). \quad (9)$$

59 where $\bar{\sigma}_a$ are the invariant 1-forms for the non-rotating frame at infinity by replacing χ in σ_a
 60 (2) with ψ . The τ -translation isometry R is interpreted to be a helical Killing vector

$$K \equiv \frac{\partial}{\partial \tau} = \frac{\partial}{\partial t} + \Omega \frac{\partial}{\partial (\psi/2)}. \quad (10)$$

61 The (E, J) phase diagram is shown in Fig. 1. The entropy S is shown by the color map.
 62 The black resonators branch off from the onset of the superradiant instability. Remarkably,
 63 they can be found even in the region where no regular Myers-Perry solutions exist. While the
 64 metric in the non-rotating frame at infinity is time dependent (9), the entropy is not. The zero
 65 horizon size limit ($r_h \rightarrow 0$) of the black resonators is given by regular horizonless solutions
 66 called geons. The entropy of the black resonators approaches zero in the geon limit. The blank
 67 region below the geon curve is not covered by our ansatz.

68 3 Photonic black resonators

69 Cohomogeneity-1 black resonators equipped with time periodic electromagnetic waves can be
 70 obtained in Einstein-Maxwell theory. On the metric (1), we turn on a $U(1)$ gauge field as

$$A = \gamma(r)\sigma_1 = \gamma(r)(\sigma_+ + \sigma_-). \quad (11)$$

71 This gives the energy-momentum tensor consistent with the metric ansatz.

72 In Fig. 2, the entropies between different solutions are compared at fixed $E = 0.2$. The
 73 gravitational and photonic black resonators branch off from the Myers-Perry black hole around

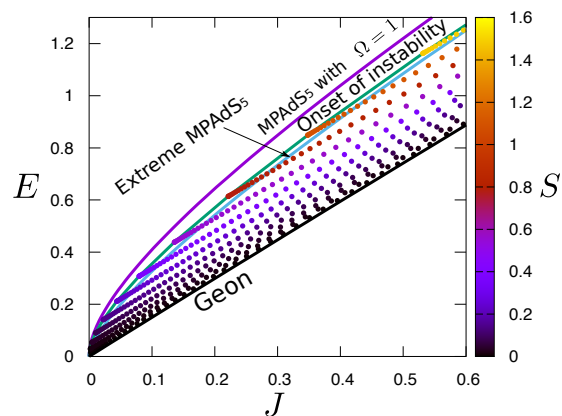

Figure 1: Phase diagram. Dots are the numerical data we constructed. The entropy S is shown by the color map.

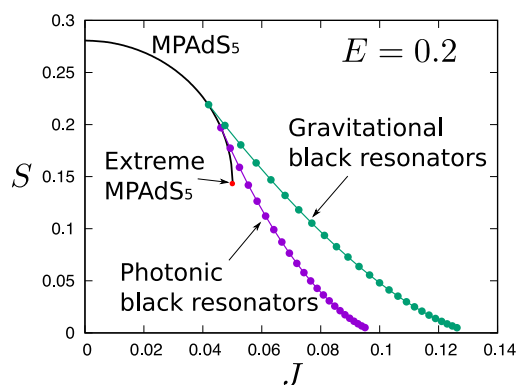

Figure 2: Entropy S of the photonic black resonators for $E = 0.2$. The entropies of gravitational black resonators and Myers-Perry-AdS black holes are also shown.

74 $J = 0.042$ and $J = 0.046$, respectively. Both solutions can exist in the region where no regular
 75 Myers-Perry black holes can. Hence the region with regular solutions in the phase diagram is
 76 extended. However, a photonic black resonator has lower entropy than a purely gravitational
 77 black resonator at the same (E, J) . This implies that the former would be further unstable
 78 against $SU(2)$ -symmetric perturbations and evolve into the latter if dynamical time evolution
 79 is considered.

80 4 Superradiant instability of black resonators

81 Black resonators obtained so far have angular frequency $\Omega > 1$. In the asymptotic infinity
 82 ($r \rightarrow \infty$), the norm of the helical Killing vector behaves as

$$K^2 = g_{\mu\nu}K^\mu K^\nu = g_{\tau\tau} \rightarrow -r^2(1 - \Omega). \tag{12}$$

83 Thus, the Killing vector is asymptotically spacelike $K^2 > 0$ because $\Omega > 1$. It has been shown
 84 that solutions with such a property should be unstable [8]. In the case of the cohomogeneity-1
 85 black resonators, we can consider perturbations breaking the $SU(2)$ isometry of the metric.

86 For simplicity, we consider only the massless scalar field perturbation in the black resonator
 87 and geon backgrounds. To find the onset of instability, it is convenient to consider the eigen-

Figure 3: Phase diagram for the stability of the black resonators against a scalar field. The colored curves correspond to the onset of an instability. Black resonators are unstable to a given mode below each curve.

88 value equation of the Klein-Gordon operator as $\square\Phi = \lambda\Phi$ and search for solutions with zero
 89 eigenvalues $\lambda = 0$.

90 The scalar field can be decomposed to modes by using the Wigner D-matrices as

$$\Phi(\tau, r, \theta, \phi, \chi) = e^{-i\omega\tau} \sum_{|k|\leq j} \phi_k(r) D_k(\theta, \phi, \chi), \quad (13)$$

91 where the indices of and summation over (j, m) are suppressed. Using this, we obtain coupled
 92 equations for ϕ_k with the following structure,

$$L_k \phi_k + c_{k-1} \phi_{k-2} + c_{k+1} \phi_{k+2} = 0, \quad (14)$$

93 where

$$L_k = (1+r^2)g \frac{d^2}{dr^2} + \left[\frac{1+r^2}{2} \left(\frac{f'}{f} + \frac{g'}{g} + \frac{\beta'}{\beta} \right) + \frac{3+5r^2}{r} \right] g \frac{d}{dr} - \frac{\epsilon_k^2 + \epsilon_{k+1}^2}{r^2} \left(\alpha + \frac{1}{\alpha} \right) - \frac{4k^2}{r^2\beta} + \frac{(\omega - 2kh)^2}{(1+r^2)f} - \lambda, \quad (15)$$

94 and

$$c_k = -\frac{\epsilon_k \epsilon_{k+1}}{r^2} \left(\alpha - \frac{1}{\alpha} \right). \quad (16)$$

95 Note that ϕ_k vanishes if $|k| > j$. If $\alpha = 1$ identically such as the Myers-Perry solution, modes
 96 with different k decouple. In contrast, different- k modes couple in the black resonator back-
 97 ground because the $U(1)$ isometry for the quantum number k is broken. The mode coupling
 98 is “double-stepping,” i.e. the mode with k is coupled to those with $k \pm 2$.

99 We solve the coupled equations (14) and identify the instability of ϕ_k in the black resonator
 100 background. For a given j , we focus on the set of modes containing the $k = j$ component,
 101 which would be the mode with the highest growth rate among those with different k . In
 102 Fig. 3, we show the location of the onsets for the superradiant instability on black resonators
 103 for modes with $j = 9/2$, $j = 5$, and $j = 11/2$. For $j = 5$, there are actually two onset curves
 104 corresponding to even and odd parity modes, but they almost coincide. In the inset, we zoom
 105 into the region near the geon where it is easier to see the difference between these modes.

106 5 Summary

107 We studied the superradiant instability of the five-dimensional Myers-Perry black hole with
108 equal angular momenta for $SU(2)$ -invariant metric perturbations. We then constructed black
109 resonators that branch off from the onset of the instability and are given by cohomogeneity-1
110 metric. In addition to gravitational black resonators in Einstein gravity, we obtained photonic
111 black resonators in Einstein-Maxwell theory. By using the cohomogeneity-1 black resonator
112 as the background, we studied the perturbation of the black resonators and identified their
113 instability.
