Abstract

We devise new boundary conditions for the near-horizon geometries of extremal BTZ and Kerr black holes, as well as for the ultra-cold limit of the Kerr-de Sitter black hole. These boundary conditions are obtained as the higher-dimensional uplift of recently proposed boundary conditions in two-dimensional gravity. Their asymptotic symmetries consist in the semi-direct product of a Virasoro and a current algebra, of which we determine the central extensions.

²² 1 Introduction and Outlook

When formulating a physical problem, the equations of motion have to be supplemented by 23 boundary conditions (BCs) on the dynamical variables. In fact, the latter turn out to be as 24 important as the former [1] (cited in [2]). This is especially clear when the theory is for-25 mulated in terms of an action principle and the partition function defined through a path 26 integral: the boundary conditions specify the off-shell configurations over which the integral 27 has to be performed. Systems with identical field equations but different boundary conditions 28 could describe significantly distinct physical phenomena and exhibit different contents (e.g. 29 closed/open strings, Dirichlet vs Neumann BCs). 30

Boundary conditions play a crucial role in gauge theories, in particular in theories of gravity. There, the set of metrics satisfying given equations of motion and boundary conditions constitute the configuration space of the theory, which can be identified with its phase space. The identification of the symmetries of the phase space are of crucial importance since one expects, upon quantization, that the Hilbert space of the corresponding quantum theory will fall into a representation of the symmetry group, for instance in the spirit of the geometric quantization program [3,4].

In gauge theories, the symmetries of the phase space, mapping one solution onto another 38 with distinct physical charges, are of great importance. These are called asymptotic symmetries 39 and form the asymptotic symmetry group (ASG). The study of asymptotic symmetries in gravity 40 theories has a long history that started in 1962 with the founding papers [5,6] which identified 41 the BMS group of supertranslations and Lorentz transformations as ASG of four-dimensional 42 asymptotically flat spacetimes. It was later extended to include superrotations in [7-9] and 43 diffeomorphisms on the 2-sphere in [10, 11]. The renewed interest in BMS symmetries is 44 largely due to recent work on BMS invariance of scattering amplitudes [12] and the "infrared 45 triangle" relating BMS supertranslation symmetries, Weinberg's soft graviton theorem and the 46 displacement memory effect [13]. 47

Equally impactful is the discovery by Brown and Henneaux of two-dimensional confor-48 mal symmetry in the asymptotic structure of AdS_3 gravity [14], an early precursor of the 49 AdS/CFT correspondence [15]. It brought deep insights into the holographic nature of gravity 50 and in particular the identification of microscopic degrees of freedom for specific classes of 51 black holes, either asymptotically AdS₃ (the BTZ black hole [16, 17]) [18] or with an AdS₃ 52 factor in their near-horizon geometry [19]. The three-dimensional situation in flat space has 53 been addressed more recently, identifying the BMS₃ asymptotic symmetry algebra at null infin-54 ity [20, 21] and at spatial infinity [22]. The flat limit from AdS₃ to Minkowski was described 55 in [21] for the symmetry algebra, and for the full phase space in [23]. The flat spacetime 56 cosmologies [24,25] - the flat counterparts of the BTZ black holes - and their thermodynam-57 ical interpretation in terms of BMS₃ symmetries were addressed in [26, 27]. Interestingly, the 58 non-uniqueness of the ASG given a vacuum solution and non-trivial zero-mode solutions has 59 been brought to light only rather recently. Superrotations in four-dimensional asymptotically 60 flat space have been introduced almost half a century after the works of Bondi, van der Burg, 61 Metzner and Sachs. In three-dimensional gravity, a variety of alternative boundary conditions 62 - allowing e.g. for a fluctuating boundary metric, in contrast with the Dirichlet-like Brown-63 Henneaux boundary conditions – have been proposed in recent years both for AdS_3 [28–33] 64 and Minkowski space [34–36] exhibiting in general different ASGs, hence potentially different 65

field theory dual interpretations. A particular way of relating different ASGs in three dimen sions has been discussed in [37].

Among holographic dualities involving AdS spaces, the two-dimensional case has always 68 stood out as more challenging. The boundary of AdS2 consists in two disconnected pieces, and 69 finite energy excitations have been observed to destroy the asymptotic geometry [38,39]. This 70 has long been a hindrance for a microscopic understanding of extremal higher-dimensional 71 black holes, as these generally exhibit a near-horizon geometry including an AdS₂ factor 72 [40, 41] when the cosmological constant is non-positive (we will later discuss a situation 73 where AdS₂ in replaced by Mink₂ for the near-horizon limit of the ultra-cold Kerr-de Sitter 74 black hole [42]). It has however recently been found how to circumvent these obstructions 75 and identify the relevant degrees of freedom describing the low energy physics driving a black 76 hole away from extremality. It consists in considering nearly-AdS₂ holography by including 77 the leading corrections away from pure AdS₂ [43, 44] (for reviews, see e.g. [45, 46] or App.B 78 of [47]). The physics near the horizon of near-extremal black holes in higher dimensions can 79 be shown to be universally described by a particular occurrence of two-dimensional dilaton 80 gravity theory – JT gravity [48,49], with certain Dirichlet boundary conditions at the boundary 81 of AdS₂. The latter exhibit time-reparametrization invariance whose generators¹ are reminis-82 cent of (one half of) the Brown-Henneaux ones [50-52]. Again, like in higher dimensions, 83 different sets of boundary conditions with different symmetries can be considered [53]. Re-84 cently, new boundary conditions for AdS₂ have been proposed [54], where the usual time-85 reparametrization symmetry is enhanced with an additional local U(1) symmetry, extending 86 the symmetry algebra to a Virasoro-Kac-Moody U(1) algebra. The latter represent the sym-87 metries of a so-called Warped CFT (WCFT) [55,56], a two-dimensional non-relativistic theory 88 with chiral scale invariance and $SL(2,R) \times U(1)$ global symmetry (see [29,57–62] for some of 89 their properties). 90

The goal of the present work will be to explore new boundary conditions for extremal black holes, in particular determine whether the boundary conditions of [54] can be uplifted to the near-horizon geometry in higher dimensions. Our work can thus be regarded as a proof of principle that certain boundary conditions existing in 2d gravity have a natural uplift to higher dimensions.

Motivations stem from the ubiquity of AdS₂ in the near-horizon geometry of extremal 96 black holes, but also from the Kerr/CFT correspondence [63] - an attempt to relate four-97 dimensional extremal Kerr black holes to a chiral CFT in two dimensions. The argument there 98 parallels the connection between AdS₃ and 2d CFTs, where the AdS₃ near-region throat geom-99 etry is replaced with the NHEK (near-horizon extreme Kerr) geometry found by Bardeen and 100 Horowitz [64] via a near-horizon limit. Constant polar sections of the NHEK geometry consist 101 in deformations of AdS₃, termed Warped AdS₃ (WAdS₃) spaces [65–71], where the original 102 undeformed SO(2,2) isometries get broken down to $SL(2,R) \times U(1)$. Holographic properties 103 of WAdS₃ spaces have been explored over the years [56, 72-88] as a toy model for Kerr black 104 holes. For generic Kerr black holes, the relevance of WCFTs was pointed out in [89] in the 105 spirit of [90]. In the extremal limit, the question is still open. 106

The Kerr/CFT proposal is based on boundary conditions extending the U(1) part of the isometry group into a Virasoro algebra, whose computed central charge allowed to reproduce the macroscopic Bekenstein-Hawking extremal Kerr entropy. This was one of the landmarks of the original proposal². From a gravity perspective these boundary conditions might seem unnatural, as their symmetries do not include all the exact symmetries of the background.

¹Note that the reparameterisation symmetry is broken both spontaneously by pure AdS_2 and explicitly due to the non-trivial boundary condition for the dilaton

²This is currently being debated in recent works suggesting instead a vanishing entropy at low temperatures [91,92].

Soon after the Kerr/CFT proposal, other boundary conditions have been proposed extending 112 instead the SL(2,R) part of the isometries, but found vanishing central extensions [93,94]. In 113 this work, we will propose new boundary conditions for the NHEK geometry, inspired by the 114 Godet-Marteau analysis in two dimensions [54]. One feature of these boundary conditions and 115 their symmetries is the dependence of the generators on (retarded) time. Extracting a non-116 trivial symmetry algebra therefore requires to integrate charges over time instead of the usual 117 constant-time, angular integration. This procedure has been applied both in two and higher 118 dimensions [51, 53, 95, 96]. Integration over time produces time-averaged charges which can 119 be seen to give a canonical representation of the asymptotic symmetry algebra with non-trivial 120 central extensions. The procedure can also be interpreted from the boundary perspective, in 121 particular when the putative dual theory is two-dimensional (CFT, WCFT, or other) and enjoys 122 modular invariance. A modular invariant field theory at finite chemical potentials is naturally 123 defined on a torus with two cycles, the spatial one (angular identifications) and the thermal 124 one (in particular, time has a period set by the inverse temperature). Its partition function can 125 be expressed either as a trace over states defined on spatial cycles (with charges integrated 126 over a spatial cycle) and evolved with the usual hamiltonian operator, or as states defined on 127 thermal cycles (hence with time periodic in particular and charges integrated over a thermal 128 cycle) and evolved with the angular momentum operator. This yields one possible boundary 129 interpretation of a bulk time integration. 130

The paper is organized as follows. As a warm-up, we devise in Sect. 2 new boundary 131 conditions for the near-horizon limit of extremal BTZ black holes, the so-called selfdual orb-132 ifold. Kerr/CFT-like boundary conditions had appeared e.g. in [97]. Here we define a new 133 phase space with WCFT symmetries of which we identify the non-trivial central extensions, 134 the Virasoro one coinciding with the Brown-Henneaux central charge. In Sect. 3 we turn to 135 boundary conditions including the NHEK geometry. Following a similar strategy, we define a 136 phase space, identify their asymptotic symmetries, and compute the asymptotic charges. The 137 latter are shown to satisfy through their Poisson bracket a WCFT algebra with non trivial cen-138 tral extensions both for the Virasoro and current algebra. The Virasoro central extensions is 139 seen to match that of the original Kerr/CFT correspondence. We address a slightly different 140 case in Sect. 4. It consists in boundary conditions including the near-horizon limit of the 141 ultra-cold Kerr-de Sitter black hole in 4 dimensions (where the 3 horizons come to coincide). 142 There is no known way to associate a CFT or any other boundary theory for that matter to 143 the ultracold limit [42] (see however [98] studying the response of ultracold black holes to 144 small perturbations). The latter does not fall in the geneal category of AdS_2 near-horizon ge-145 ometry. Instead, the AdS₂ factor is replaced by two-dimensional Minkowski space. As it turns 146 out, boundary conditions for Mink₂ have been proposed and their asymptotic symmetries de-147 termined [99, 100]. We uplift these boundary conditions to 4 dimensions, demonstrating that 148 they yield well defined charges and asymptotic symmetry algebras, again consisting in a WCFT 149 algebra of which we compute the central extensions. This provides a first step towards building 150 a holographic dual for ultracold Kerr-dS black holes. The implications of these new boundary 151 conditions from a boundary perspective and black hole thermodynamics in particular is left 152 for future work. 153

154 **2 Extremal BTZ**

155 2.1 Geometry and Near-horizon Limit

¹⁵⁶ The metric of the extremal BTZ black hole is

$$ds^{2} = -\frac{(r^{2} - r_{h}^{2})^{2}}{r^{2}}dt^{2} + \frac{r^{2}}{(r^{2} - r_{h}^{2})^{2}}dr^{2} + r^{2}\left(d\phi - \frac{r_{h}^{2}}{r^{2}}dt\right)^{2},$$
(1)

where r_h is the horizon radius and where the AdS radius *l* has been set to one. We consider the change of coordinates

$$t = \frac{\tau}{\epsilon}, \quad r^2 = r_h^2 + \epsilon \rho, \quad \phi = \varphi + \frac{\tau}{\epsilon}$$
 (2)

and then study the near-horizon limit (NHL) by taking $\epsilon \rightarrow 0$. The extremal BTZ metric becomes [101]

$$ds^{2} = \frac{1}{4} \frac{d\rho^{2}}{\rho^{2}} + 2\rho d\tau d\varphi + r_{h}^{2} d\varphi^{2}$$

= $\frac{1}{4} \frac{d\rho^{2}}{\rho^{2}} - \frac{\rho^{2}}{r_{h}^{2}} d\tau^{2} + r_{h}^{2} \left(d\varphi + \frac{\rho}{r_{h}^{2}} d\tau \right)^{2}.$ (3)

In order to apply Godet-Marteau boundary conditions on this metric, we will write it in a system of coordinates that is similar to the Bondi gauge described in [54] for AdS₂. We thus define new coordinates $(u, \hat{r}, \hat{\varphi})$ such that

$$\tau = \frac{u}{2} - \frac{1}{2\hat{r}}, \quad \rho = r_h \hat{r}, \quad \varphi = \frac{1}{2r_h} (\hat{\varphi} - \ln \hat{r})$$
 (4)

164 and the metric becomes

$$ds^{2} = \frac{1}{4}(-\hat{r}^{2}du^{2} - 2dud\hat{r}) + \frac{1}{4}(\hat{r}du + d\hat{\varphi})^{2}.$$
(5)

From now on, we will omit "^" of the coordinates, keeping in mind that the new coordinates are different from the ones in (3).

167 2.2 Phase Space and Asymptotic Killing Vectors

Inspired by the Godet-Marteau boundary conditions for AdS_2 [54], we consider the following family of metrics

$$ds^{2} = \frac{1}{4} \left((-r^{2} + 2P(u)r + 2T(u))du^{2} - 2dudr \right) + \frac{1}{4} (rdu + d\varphi)^{2},$$
(6a)

$$= ds_{2d}^{2} + \frac{1}{4}(rdu + d\varphi)^{2}$$
(6b)

where *P* and *T* are arbitrary functions of *u*. Here, the first part of the metric ds_{2d}^2 corresponds to boundary conditions that were previously imposed for 2d gravity [54]. The boundary conditions (6) can be obtained from (5) by applying the finite coordinate transformation

$$u \to \mathcal{F}(u), \quad r \to \frac{1}{\mathcal{F}'}(r + \mathcal{G}'(u)), \quad \varphi \to \varphi - \mathcal{G}(u).$$
 (7)

$$P(u) = -\mathcal{G}'(u) + \frac{\mathcal{F}''(u)}{\mathcal{F}'(u)},$$
(8)

$$T(u) = -\frac{1}{2}\mathcal{G}'(u)^2 + \mathcal{G}'(u)\frac{\mathcal{F}''(u)}{\mathcal{F}'(u)} - \mathcal{G}''(u).$$
(9)

¹⁷⁴ The asymptotic Killing vectors generating the transformations (7) are given by

$$\xi = \epsilon(u)\partial_u + (-r\epsilon'(u) - \zeta'(u))\partial_r + \zeta(u)\partial_{\varphi}, \qquad (10)$$

where $\epsilon(u)$ and $\zeta(u)$ are two arbitrary functions of u. By applying the Lie derivative on the metric (6), we can also find the variations of P(u) and T(u)

$$\delta_{\xi} P = \epsilon P' + \epsilon' P + \epsilon'' + \zeta', \qquad (11)$$

$$\delta_{\xi}T = \epsilon T' + 2\epsilon' T - \zeta' P + \zeta''.$$
(12)

177 Alternatively, we can define a perturbation $h_{\mu\nu}$ on the background metric (5) such that

$$h_{uu} = \mathcal{O}(r), \quad h_{ur} = \mathcal{O}(r^{-2}), \quad h_{u\varphi} = \mathcal{O}(r^{-1}),$$
 (13a)

$$h_{rr} = \mathcal{O}(r^{-3}), \quad h_{r\varphi} = \mathcal{O}(r^{-2}), \quad h_{\varphi\varphi} = \mathcal{O}(r^{-1})$$
 (13b)

and the vectors solving the asymptotic Killing equation are given by

$$\xi = (\epsilon(u) + \mathcal{O}(r^{-2})) \partial_u + (-r\epsilon'(u) - \zeta'(u) + \mathcal{O}(r^{-1})) \partial_r + (\zeta(u) + \mathcal{O}(r^{-2})) \partial_{\varphi}.$$
(14)

Fixing the coordinate system, by setting $g_{ur} = -1/4$, $g_{rr} = 0$ and $g_{r\varphi} = 0$, and assuming that the remaining components admit an expansion in powers of r

$$g_{uu} = rg_{uu1}(u,\varphi) + g_{uu0}(u,\varphi) + \mathcal{O}(r^{-1}), \qquad (15a)$$

$$g_{u\varphi} = \frac{r}{4} + \frac{g_{u\varphi 0}(u,\varphi)}{r} + \mathcal{O}(r^{-2}), \qquad (15b)$$

$$g_{\varphi\varphi} = \frac{1}{4} + \frac{g_{\varphi\varphi-1}(u,\varphi)}{r} + \mathcal{O}(r^{-2}), \qquad (15c)$$

one readily obtains that (6) is the unique class of metrics that solves the vacuum Einstein
equations with a negative cosmological constant and the fall-off conditions (13). It is in this
sense, that (13) and (14) are equivalent to (6) and (10). In the following, we will always work
with a class of metrics instead of directly working with boundary conditions.

From now on, we assume that u is periodic with period L and define the modes of the vectors (10) as

$$l_n = \xi \left(\epsilon = \frac{L}{2\pi} e^{2\pi i n u/L}, \ \zeta = 0 \right), \quad j_n = \xi \left(\epsilon = 0, \ \zeta = \frac{L}{2\pi i} e^{2\pi i n u/L} \right), \tag{16}$$

where $n \in \mathbb{Z}$. These modes satisfy a warped Witt algebra under the Lie bracket:

$$i[l_m, l_n] = (m-n)l_{m+n},$$
 (17a)

$$i[l_m, j_n] = -nj_{m+n},$$
 (17b)

$$i[j_m, j_n] = 0.$$
 (17c)

188 2.3 Charge Algebra

The infinitesimal charge difference between two geometries $g_{\mu\nu}$ and $g_{\mu\nu} + h_{\mu\nu}$, where $h_{\mu\nu}$ is an infinitesimal perturbation, is given by

$$\delta Q_{\xi}[h,g] = \int_{\partial \Sigma} k_{\xi}[h,g].$$
(18)

¹⁹¹ The differential form k_{ξ} associated to an asymptotic Killing vector ξ is defined by³

$$k_{\xi}[h,g] = \frac{\sqrt{-g}}{8\pi G} (d^{n-2}x)_{\mu\nu} \Big(\xi^{\mu} \nabla_{\sigma} h^{\nu\sigma} - \xi^{\mu} \nabla^{\nu} h + \xi_{\sigma} \nabla^{\nu} h^{\mu\sigma} + \frac{1}{2} h \nabla^{\nu} \xi^{\mu} - h^{\rho\nu} \nabla_{\rho} \xi^{\mu} \Big), \quad (19)$$

where *n* is the space-time dimension, ∇ is the covariant derivative of $g_{\mu\nu}$ and $h = g^{\mu\nu}h_{\mu\nu}$. One readily checks that integrating (18) along the direction of φ over a constant *u* surface and taking the limit $r \to \infty$, yields zero – all surface charges vanish. One may obtain non-zero surface charges by integrating (18) along the direction of *u* over a constant φ surface and then taking the limit $r \to \infty$, which is what we will do in what follows.

¹⁹⁷ We begin by defining the variation of the metric (6) as

$$h_{\mu\nu} \equiv \delta g_{\mu\nu} = \frac{\partial g_{\mu\nu}}{\partial P} \delta P + \frac{\partial g_{\mu\nu}}{\partial T} \delta T.$$
⁽²⁰⁾

¹⁹⁸ Computing the variation of the charges, we find

$$\delta Q_{\xi} = \frac{1}{16\pi G} \int_{0}^{L} du (\epsilon \delta T - \zeta \delta P).$$
⁽²¹⁾

¹⁹⁹ We see that this expression can be directly integrated in order to obtain the finite charges

$$Q_{\xi} = \frac{1}{16\pi G} \int_{0}^{L} du(T(u)\epsilon(u) - P(u)\zeta(u)),$$
(22)

where the metric of the extremal black hole in the NHL, which has P(u) = T(u) = 0, has been chosen as the background metric. In particular, we define

$$L_n = Q_{l_n} = \frac{1}{16\pi G} \int_0^L du \, T(u) \frac{L}{2\pi} e^{2\pi i n u/L},$$
(23)

$$J_n = Q_{j_n} = -\frac{1}{16\pi G} \int_0^L du P(u) \frac{L}{2\pi i} e^{2\pi i n u/L},$$
(24)

²⁰² Computing the algebra of these charges under the Dirac bracket yields

$$i\{L_m, L_n\} = i\delta_{l_n}L_m = (m-n)L_{m+n},$$
(25a)

$$i\{L_m, J_n\} = i\delta_{j_n}L_m = -nJ_{m+n} - \frac{L}{16\pi G}m^2\delta_{m+n,0},$$
(25b)

$$i\{J_m, J_n\} = i\delta_{j_n}J_m = \frac{L^2}{32\pi^2 G}m\delta_{m+n,0}.$$
 (25c)

The algebra described by the relations (25) corresponds to a Virasoro-Kac-Moody U(1)algebra, the symmetry algebra of a WCFT,

$$i\{L_m, L_n\} = (m-n)L_{m+n} + \frac{c}{12}m^3\delta_{m+n,0}, \qquad (26a)$$

$$i\{L_m, J_n\} = -nJ_{m+n} - i\kappa m^2 \delta_{m+n,0},$$
 (26b)

$$i\{J_m, J_n\} = \frac{k}{2} m \delta_{m+n,0}.$$
 (26c)

³See e.g. [102] for a pedagogical account and references

²⁰⁵ with central charges c, κ and k

$$c = 0, \quad \kappa = \frac{L}{16\pi i G}, \quad k = \frac{L^2}{16\pi^2 G}.$$
 (27)

206 2.4 Boundary Conditions in Schwarzschild-like Coordinates

Previously, we applied the Godet-Marteau boundary conditions on the extremal BTZ black hole by introducing a new system of coordinates (with a retarded time *u*). With this system of coordinates, the metric was written in a form that was similar to the Bondi gauge for AdS₂. Here, we perform our analysis in the Schwarzschild-like system of coordinates. In these coordinates, the metric of the extremal BTZ black hole (in the NHL) reads (3). Upon rescaling $\rho \rightarrow (r_h \rho)/2$ and $\varphi \rightarrow \varphi/(2r_h)$, the metric (3) becomes

$$ds^{2} = \frac{1}{4} \left(\frac{d\rho^{2}}{\rho^{2}} - \rho^{2} d\tau^{2} \right) + \frac{1}{4} (d\varphi + \rho d\tau)^{2}.$$
 (28)

²¹³ We now impose Godet-Marteau boundary conditions on this metric by applying a finite coor-

²¹⁴ dinate transformation given by

$$\tau \to \mathcal{F}(\tau), \quad \rho \to \frac{1}{\mathcal{F}'}(\rho + \mathcal{G}'(\tau)), \quad \varphi \to \varphi - \mathcal{G}(\tau).$$
 (29)

Defining a function $\mathcal{H}(\tau) \equiv \mathcal{F}''(\tau) / \mathcal{F}'(\tau)$, this transformation yields the metric components

$$g_{\tau\tau} = -\frac{1}{2}\rho \mathcal{G}'(\tau) - \frac{1}{4}\mathcal{G}'(\tau)^2 + \frac{((\rho + \mathcal{G}'(\tau))\mathcal{H}(\tau) - \mathcal{G}''(\tau))^2}{4(\rho + \mathcal{G}'(\tau))^2},$$
(30a)

$$g_{\tau\rho} = \frac{-(\rho + \mathcal{G}'(\tau))\mathcal{H}(\tau) + \mathcal{G}''(\tau)}{4(\rho + \mathcal{G}'(\tau))^2}, \quad g_{\tau\varphi} = \frac{\rho}{4},$$
(30b)

$$g_{\rho\rho} = \frac{1}{4(\rho + \mathcal{G}'(\tau))^2}, \quad g_{\rho\varphi} = 0, \quad g_{\varphi\varphi} = \frac{1}{4}.$$
 (30c)

The metric of the extremal BTZ black hole (in the NHL) corresponds to (30) with $\mathcal{G}'(\tau) = 0$ and $\mathcal{H}(\tau) = 0$.

The asymptotic Killing vectors generating the transformations (29) are given by

$$\xi = \epsilon(\tau)\partial_{\tau} - (\rho \epsilon'(\tau) + \zeta'(\tau))\partial_{\rho} + \zeta(\tau)\partial_{\varphi}, \qquad (31)$$

where $\epsilon(\tau)$ and $\zeta(\tau)$ are two arbitrary functions of τ . By applying the Lie derivative on the metric, we find the variations of $\mathcal{G}'(\tau)$ and $\mathcal{H}(\tau)$:

$$\delta_{\xi} \mathcal{G}'(\tau) = \epsilon'(\tau) \mathcal{G}'(\tau) + \epsilon(\tau) \mathcal{G}''(\tau) - \zeta'(\tau), \qquad (32)$$

$$\delta_{\xi} \mathcal{H}(\tau) = \epsilon'(\tau) \mathcal{H}(\tau) + \epsilon''(\tau) + \epsilon(\tau) \mathcal{H}'(\tau).$$
(33)

In the following, we assume that τ is periodic with period *L*. We define modes as

$$l_n = \xi \left(\epsilon = \frac{L}{2\pi} e^{2\pi i n \tau/L}, \ \zeta = 0 \right), \quad j_n = \xi \left(\epsilon = 0, \ \zeta = \frac{L}{2\pi i} e^{2\pi i n \tau/L} \right). \tag{34}$$

²²² Under the Lie bracket, these modes satisfy the warped Witt algebra (17).

Here, the integral considered in (18) for the computation of the charges is taken over τ while $\rho \to \infty$ and φ is constant. Explicitly computing the charges yields

$$Q_{\xi} = \frac{1}{32\pi G} \int_{0}^{L} d\tau \left(2\zeta(\tau)\mathcal{G}'(\tau) - \epsilon(\tau)\mathcal{G}'(\tau)^{2} + 2\epsilon'(\tau)\mathcal{H}(\tau) + \epsilon(\tau)\mathcal{H}(\tau)^{2} \right), \quad (35)$$

where the metric of the extremal black hole in the NHL, which has $\mathcal{G}'(\tau) = \mathcal{H}(\tau) = 0$, has been chosen as the background metric. We define

$$L_n = Q_{l_n} = \frac{1}{32\pi G} \int_0^L d\tau \left(-\mathcal{G}'(\tau)^2 + \frac{4\pi i n}{L} \mathcal{H}(\tau) + \mathcal{H}(\tau)^2 \right) \frac{L}{2\pi} e^{2\pi i n \tau/L}, \quad (36)$$

$$J_n = Q_{j_n} = \frac{1}{32\pi G} \int_0^L d\tau (2\mathcal{G}'(\tau)) \frac{L}{2\pi i} e^{2\pi i n\tau/L} \,. \tag{37}$$

²²⁷ The algebra of the charges L_n and J_n is given by (26a)-(26c) with central charges

$$c^* = \frac{3}{2G}, \quad \kappa^* = 0, \quad k^* = \frac{L^2}{16\pi^2 G},$$
 (38)

which are different from those found in (27). We would like to know if it is possible to relate algebras (26) with different central charges, given by (27) and (38), respectively. By defining new surface charges [54]

$$L_n^* := L_n + \frac{2i\kappa}{k} n J_n \tag{39}$$

it is possible to go from an algebra with central charges c, κ and k to a new algebra with central charges given by

$$c^* = c - \frac{24\kappa^2}{k}, \quad \kappa^* = 0, \quad k^* = k.$$
 (40)

Using this relation, the central charges found here, (c^*, κ^*, k^*) , can be related to those found in (27), (c, κ, k) . Explicitly, we have

$$c^* = 0 - 24 \left(\frac{-L^2}{(16\pi)^2 G^2} \right) \frac{16\pi^2 G}{L^2} = \frac{3}{2G}$$
(41)

and the relations for κ^* and k^* are trivial. Note that c^* is recognized as the Brown-Henneaux central charge for AdS₃ gravity [14].

237 **3 Extremal Kerr**

238 3.1 Geometry and NHEK

The analysis of the previous sections can also be applied to extremal Kerr black holes. The metric of the extremal Kerr black hole in Boyer-Lindquist coordinates reads

$$ds^{2} = -\frac{\Delta}{\rho^{2}}(dt - a\sin^{2}\theta d\phi)^{2} + \frac{\sin^{2}\theta}{\rho^{2}}((r^{2} + a^{2})d\phi - adt)^{2} + \frac{\rho^{2}}{\Delta}dr^{2} + \rho^{2}d\theta^{2}, \quad (42)$$

241 where

$$\Delta = (r-a)^2, \quad \rho^2 = r^2 + a^2 \cos^2 \theta, \quad a = GM.$$
(43)

²⁴² We consider the change of coordinates

$$\hat{r} = \frac{r - GM}{\lambda GM}, \quad \hat{t} = \frac{\lambda t}{2GM}, \quad \hat{\phi} = \phi - \frac{t}{2GM}$$
(44)

and take the limit $\lambda \rightarrow 0$, yielding the near-horizon extremal Kerr (NHEK) geometry

$$ds^{2} = G^{2}M^{2}(1 + \cos^{2}\theta)\left(\frac{d\hat{r}^{2}}{\hat{r}^{2}} + d\theta^{2} - \hat{r}^{2}d\hat{t}^{2}\right) + \frac{4G^{2}M^{2}\sin^{2}\theta}{1 + \cos^{2}\theta}(d\hat{\phi} + \hat{r}d\hat{t})^{2}.$$
 (45)

Hereafter, we will omit "^" of the coordinates. In order to apply Godet-Marteau boundary conditions to this metric, we write it in a system of coordinates similar to the Bondi coordinates

$$t = u - \frac{1}{r}, \quad \phi = \varphi - \ln r, \qquad (46)$$

such that the metric becomes

$$ds^{2} = G^{2}M^{2}(1 + \cos^{2}\theta)(-r^{2}du^{2} - 2dudr + d\theta^{2}) + \frac{4G^{2}M^{2}\sin^{2}\theta}{1 + \cos^{2}\theta}(d\varphi + rdu)^{2}.$$
 (47)

247 3.2 Phase Space and Asymptotic Killing Vectors

Inspired by the Godet-Marteau boundary conditions for AdS_2 [54], we consider the following family of metrics

$$ds^{2} = G^{2}M^{2}(1 + \cos^{2}\theta)((-r^{2}du^{2} + 2P(u)r + 2T(u))du^{2} - 2dudr + d\theta^{2}) + \frac{4G^{2}M^{2}\sin^{2}\theta}{1 + \cos^{2}\theta}(d\varphi + rdu)^{2},$$
(48)

where *P* and *T* are arbitrary functions of *u*. They can be obtained from (47) by applying a finite coordinate transformation given by

$$u \to \mathcal{F}(u), \quad r \to \frac{1}{\mathcal{F}'}(r + \mathcal{G}'(u)), \quad \varphi \to \varphi - \mathcal{G}(u), \quad \theta \to \theta.$$
 (49)

²⁵² The functions P, T, \mathcal{F} and \mathcal{G} are related by

$$P(u) = -\mathcal{G}'(u) + \frac{\mathcal{F}''(u)}{\mathcal{F}'(u)},$$
(50)

$$T(u) = -\frac{1}{2}\mathcal{G}'(u)^2 + \mathcal{G}'(u)\frac{\mathcal{F}''(u)}{\mathcal{F}'(u)} - \mathcal{G}''(u).$$
(51)

²⁵³ The asymptotic Killing vectors generating the transformations (49) are given by

$$\xi = \epsilon(u)\partial_u - (r\epsilon'(u) + \zeta'(u))\partial_r + \zeta(u)\partial_\varphi, \qquad (52)$$

where $\epsilon(u)$ and $\zeta(u)$ are two arbitrary functions of u. By applying the Lie derivative on the metric (48), we can also find

$$\delta_{\xi} P = \epsilon P' + \epsilon' P + \epsilon'' + \zeta', \tag{53}$$

$$\delta_{\xi}T = \epsilon T' + 2\epsilon' T - \zeta' P + \zeta''.$$
(54)

From now on we assume that u is periodic with period L. We define the modes

$$l_n = \xi \left(\frac{L}{2\pi} e^{2\pi i n u/L}, 0 \right), \quad j_n = \xi \left(0, \frac{L}{2\pi i} e^{2\pi i n u/L} \right), \tag{55}$$

where $n \in \mathbb{Z}$. Under the Lie bracket, these modes satisfy the warped Witt algebra (17).

258 3.3 Charge Algebra

We can now compute the surface charges by using the expression (18). For this, we integrate over *u* and θ while keeping φ fixed and taking $r \to \infty$. Defining

$$h_{\mu\nu} \equiv \delta g_{\mu\nu} = \frac{\partial g_{\mu\nu}}{\partial P} \delta P + \frac{\partial g_{\mu\nu}}{\partial T} \delta T , \qquad (56)$$

261 we compute

$$\delta Q_{\xi} = \frac{G^2 M^2}{4\pi G} \int_0^L du \int_0^{\pi} d\theta \sin \theta (\delta T \, \epsilon - \delta P \, \zeta), \tag{57}$$

²⁶² which upon integration yields

$$Q_{\xi} = \frac{GM^2}{2\pi} \int_0^L du(T(u)\epsilon(u) - P(u)\zeta(u)), \qquad (58)$$

where the NHEK geometry, which has P(u) = T(u) = 0, has been chosen as the background metric. In particular, we define

$$L_{n} = Q_{l_{n}} = \frac{GM^{2}}{2\pi} \int_{0}^{L} du T(u) \frac{L}{2\pi} e^{2\pi i n u/L},$$
(59)

$$J_n = Q_{j_n} = -\frac{GM^2}{2\pi} \int_0^L du P(u) \frac{L}{2\pi i} e^{2\pi i n u/L}.$$
 (60)

The charges L_n and J_n respect the algebra (26) with central charges given by

$$c = 0, \quad \kappa = \frac{LGM^2}{2\pi i}, \quad k = \frac{L^2GM^2}{2\pi^2}.$$
 (61)

266 3.4 Boundary Conditions in Boyer-Lindquist Coordinates

So far, we studied the NHEK geometry by writing it in a new system of coordinates (with a retarded time u). Now, we perform the same analysis in Boyer-Lindquist coordinates. Again, we obtain a phase space of metrics from (45) by applying the finite coordinate transformation

$$t \to \mathcal{F}(t), \quad r \to \frac{1}{\mathcal{F}'}(r + \mathcal{G}'(t)), \quad \phi \to \phi - \mathcal{G}(t).$$
 (62)

Defining $\mathcal{H}(t) \equiv \mathcal{F}''(t)/\mathcal{F}'(t)$, yields

$$g_{tt} = \frac{4r^2 G^2 M^2 \sin^2 \theta}{1 + \cos^2 \theta} - G^2 M^2 (1 + \cos^2 \theta) (r + \mathcal{G}'(t))^2 + \frac{G^2 M^2 (1 + \cos^2 \theta)}{(r + \mathcal{G}'(t))^2} ((r + \mathcal{G}'(t)) \mathcal{H}(t) - \mathcal{G}''(t))^2,$$
(63a)

$$g_{tr} = -G^2 M^2 (1 + \cos^2 \theta) \frac{((r + \mathcal{G}'(t))\mathcal{H}(t) - \mathcal{G}''(t))}{(r + \mathcal{G}'(t))^2},$$
(63b)

$$g_{t\theta} = 0$$
, $g_{t\phi} = \frac{4rG^2M^2\sin^2\theta}{1+\cos^2\theta}$, (63c)

$$g_{rr} = \frac{G^2 M^2 (1 + \cos^2 \theta)}{(r + \mathcal{G}'(t))^2}, \quad g_{r\theta} = 0, \quad g_{r\phi} = 0,$$
(63d)

$$g_{\theta\theta} = G^2 M^2 (1 + \cos^2 \theta), \quad g_{\theta\phi} = 0, \quad g_{\phi\phi} = \frac{4G^2 M^2 \sin^2 \theta}{1 + \cos^2 \theta},$$
 (63e)

where the NHEK geometry is obtained by setting $\mathcal{G}'(t) = 0$ and $\mathcal{H}(t) = 0$. Hence, the order of the non-zero fluctuations of the boundary metric is given by

$$h_{tt} = \mathcal{O}(r), \quad h_{tr} = \mathcal{O}(r^{-1}), \quad h_{rr} = \mathcal{O}(r^{-3}).$$
 (64)

²⁷³ The asymptotic Killing vectors generating the transformations (62) are given by

$$\xi(\epsilon,\zeta) = \epsilon(t)\partial_t + (-r\epsilon'(t) - \zeta'(t))\partial_r + \zeta(t)\partial_\phi, \qquad (65)$$

where $\epsilon(t)$ and $\zeta(t)$ are two arbitrary functions of *t*.

We recall that the group of exact isometries of the NHEK geometry, $SL(2,\mathbb{R}) \times U(1)$, is generated by the Killing vectors

$$\xi_{-1} = \partial_t \,, \quad \xi_0 = t \partial_t - r \partial_r \,, \quad \xi_1 = \left(t^2 + \frac{1}{r^2}\right) \partial_t - 2tr \partial_r - \frac{2}{r} \partial_\phi \,, \tag{66}$$

$$\xi_{\phi} = \partial_{\phi} \,. \tag{67}$$

²⁷⁷ Comparing these vectors with (65), we find that $\xi_{-1} = \xi(\epsilon = 1, \zeta = 0)$, $\xi_0 = \xi(\epsilon = t, \zeta = 0)$, ²⁷⁸ $\xi_{\phi} = \xi(\epsilon = 0, \zeta = 1)$ and that ξ_1 correspond to $\xi(\epsilon = t^2, \zeta = 0)$ up to subleading terms ²⁷⁹ in *r*. Hence, the asymptotic symmetry group contains all the exact isometries of the NHEK ²⁸⁰ geometry, which was not the case for the boundary conditions studied in [63]. ²⁸¹ By applying the Lie derivative on (63), we find

$$\delta_{\xi} \mathcal{G}'(t) = \epsilon'(t) \mathcal{G}'(t) + \epsilon(t) \mathcal{G}''(t) - \zeta'(t), \tag{68}$$

$$\delta_{\xi} \mathcal{H}(t) = \epsilon'(t) \mathcal{H}(t) + \epsilon''(t) + \epsilon(t) \mathcal{H}'(t).$$
(69)

From now on we assume that t is periodic with period L. We define modes as

$$l_n = \xi \left(\frac{L}{2\pi} e^{2\pi i n t/L}, 0 \right), \quad j_n = \xi \left(0, \frac{L}{2\pi i} e^{2\pi i n t/L} \right), \tag{70}$$

with $n \in \mathbb{Z}$, which satisfy (17).

Here, the integral considered in (18) for the computation of the charges is taken over *t* and θ while $r \to \infty$ and ϕ is constant. Computing the charges explicitly, we find

$$Q_{\xi} = \frac{GM^2}{4\pi} \int_0^L dt (2\mathcal{G}'(t)\zeta(t) - \mathcal{G}'(t)^2\epsilon(t) + 2\epsilon'(t)\mathcal{H}(t) + \epsilon(t)\mathcal{H}(t)^2), \tag{71}$$

where the NHEK geometry, which has G'(t) = H(t) = 0, has been chosen as the background metric. In particular, we define

$$L_n = Q_{l_n} = \frac{GM^2}{4\pi} \int_0^L dt \left(-\mathcal{G}'(t)^2 + \frac{4\pi i n}{L} \mathcal{H}(t) + \mathcal{H}(t)^2 \right) \frac{L}{2\pi} e^{2\pi i n t/L},$$
(72)

$$J_n = Q_{j_n} = \frac{GM^2}{4\pi} \int_0^L dt \ 2 \ \mathcal{G}'(t) \ \frac{L}{2\pi i} e^{2\pi i n t/L}.$$
(73)

The charges L_n and J_n fulfill the algebra (26) with central charges given by

$$c^* = 12GM^2 = 12J$$
, $\kappa^* = 0$, $k^* = \frac{L^2 GM^2}{2\pi^2} = \frac{JL^2}{2\pi^2}$. (74)

The algebra (26) with central charges (74), (c^*, κ^*, k^*) can be related to the one with central charges (61), (c, κ, k) , by the transformation (39) and (40). Indeed, we have

$$c^* = 0 - 24 \left(\frac{LGM^2}{2\pi i}\right)^2 \frac{2\pi^2}{L^2 GM^2} = 12GM^2$$
(75)

and the relations for κ^* and k^* are trivial. Here c^* is recognized as the Kerr/CFT central charge [63].

293 3.5 Comparison to other Boundary Conditions for extremal Kerr Black Holes

We now compare our results with those obtained in [93]. There, the perturbations defined on the background metric (45) were

$$h_{tt} = \mathcal{O}(r^0), \qquad h_{tr} = \mathcal{O}(r^{-3}), \qquad h_{t\theta} = \mathcal{O}(r^{-3}), \qquad h_{t\phi} = \mathcal{O}(r^{-2}),$$
(76a)

$$h_{rr} = \mathcal{O}(r^{-4}), \qquad h_{r\theta} = \mathcal{O}(r^{-4}), \qquad h_{r\phi} = \mathcal{O}(r^{-3}),$$
(76b)

$$h_{\theta\theta} = \mathcal{O}(r^{-3}), \qquad h_{\theta\phi} = \mathcal{O}(r^{-3}), \qquad h_{\phi\phi} = \mathcal{O}(r^{-2})$$
(76c)

²⁹⁶ and the vectors solving the asymptotic Killing equation took the general form

$$\xi = \left(\epsilon(t) + \frac{\epsilon''(t)}{2r^2} + \mathcal{O}(r^{-3})\right)\partial_t + \left(-r\epsilon'(t) + \frac{\epsilon'''(t)}{2r} + \mathcal{O}(r^{-2})\right)\partial_r + \left(\mathcal{C} - \frac{\epsilon''(t)}{r} + \mathcal{O}(r^{-3})\right)\partial_\phi + \mathcal{O}(r^{-3})\partial_\theta,$$
(77)

where $\epsilon(t)$ is an arbitrary function of t and C is an arbitrary constant. The boundary conditions (76) are different from ours, compare equation (64). Neglecting the subleading terms, we see that (65) reduces to (77) upon setting $\zeta(t) = C = \text{const.}$ Hence, in both cases the expression (77) contains the vectors (66)-(67) generating the $SL(2, \mathbb{R}) \times U(1)$ group of isometries.

In [93] it is claimed that the charges associated to the vectors (77) with C = 0 form a Virasoro algebra with vanishing central extension, contrary to our result. Indeed, restricting to a subset of our charges by considering only asymptotic Killing vectors (65) that have $\zeta(t) = 0$, we obtain a Virasoro algebra (26a) with non-zero central charge.

Different boundary conditions encompassing the NHEK geometry were also presented in [103, 104]. Starting from the background metric (45), a phase space of metrics was obtained by applying a finite coordinate transformation

$$t \to f(t) + \frac{2f''(t)f'(t)^2}{4r^2 f'(t)^2 - f''(t)^2},$$

$$r \to \frac{4r^2 f'(t)^2 - f''(t)^2}{4r f'(t)^3},$$

$$\phi \to \phi + \log\left(\frac{2rf'(t) - f''(t)}{2rf'(t) + f''(t)}\right),$$
(78)

308 yielding the line element

$$ds^{2} = G^{2}M^{2}(1 + \cos^{2}\theta) \left(-r^{2} \left(1 + \frac{\{f(t), t\}}{2r^{2}} \right)^{2} dt^{2} + \frac{dr^{2}}{r^{2}} + d\theta^{2} \right) + \frac{4G^{2}M^{2}\sin^{2}\theta}{1 + \cos^{2}\theta} \left(d\phi + r \left(1 - \frac{\{f(t), t\}}{2r^{2}} \right) dt \right)^{2}$$
(79)

309 with the Schwarzian derivative

$$\{f(t), t\} = \left(\frac{f''}{f'}\right)' - \frac{1}{2} \left(\frac{f''}{f'}\right)^2.$$
(80)

310 Equivalently, the components of this metric read

$$g_{tt} = \frac{4r^2 G^2 M^2 \sin^2 \theta}{1 + \cos^2 \theta} \left(1 - \frac{\{f(t), t\}}{2r^2} \right)^2 - G^2 M^2 (1 + \cos^2 \theta) r^2 \left(1 + \frac{\{f(t), t\}}{2r^2} \right)^2, \quad (81a)$$

$$g_{tr} = 0, \quad g_{t\theta} = 0, \quad g_{t\phi} = \frac{4G^2 M^2 \sin^2 \theta}{1 + \cos^2 \theta} r \left(1 - \frac{\{f(t), t\}}{2r^2} \right),$$
 (81b)

$$g_{rr} = \frac{G^2 M^2 (1 + \cos^2 \theta)}{r^2}, \quad g_{r\theta} = 0, \quad g_{r\phi} = 0,$$
 (81c)

$$g_{\theta\theta} = G^2 M^2 (1 + \cos^2 \theta), \quad g_{\theta\phi} = 0, \quad g_{\phi\phi} = \frac{4G^2 M^2 \sin^2 \theta}{1 + \cos^2 \theta},$$
 (81d)

which are different from the components (63) that we obtained from applying the transformation (62). The order of the non-zero fluctuations of the boundary metric

$$h_{tt} = \mathcal{O}(r^{-2}), \quad h_{t\varphi} = \mathcal{O}(r^{-1}) \tag{82}$$

are different from (76) and ours, compare equation (64). Furthermore, while here the components only depend on one free function of *t*, our class of metrics (63a)-(63e) depends on two. Expanding $f(t) = t + \epsilon(t) + O(\epsilon^2)$, the asymptotic Killing vectors generating the transformations (78) are given by

$$\xi = \left(\epsilon(t) + \frac{\epsilon''(t)}{2r^2}\right)\partial_t - r\epsilon'(t)\partial_r - \frac{\epsilon''(t)}{r}\partial_\phi, \qquad (83)$$

where $\epsilon(t)$ is an arbitrary function of *t*. Again, up to subleading terms, these vectors are a subset of the vectors (65), obtained by setting $\zeta(t) = 0$.

319 4 Ultra-cold Kerr-dS

320 4.1 Geometry and Phase Space

In this section, we study the near horizon geometry of the Kerr-dS black hole in the ultracold limit where the inner, outer and cosmological horizon coincide. In this limit, the metric takes the form [42]

$$\frac{ds^2}{\ell^2} = \Gamma(\theta) \Big(-dt^2 + dr^2 + \alpha(\theta)d\theta^2 \Big) + \gamma(\theta)(d\phi + \bar{k}rdt)^2$$
(84)

324 with

$$\Gamma(\theta) = \frac{\sqrt{2\sqrt{3} - 3}\left(\left(3 - 2\sqrt{3}\right)\cos^2(\theta) - 1\right)}{2\left(\sqrt{3} - 3\right)}, \qquad \alpha(\theta) = \frac{2\sqrt{14\sqrt{3} - 24}}{\left(7\sqrt{3} - 12\right)\cos^2(\theta) + \sqrt{3}}, \quad (85)$$

$$\gamma(\theta) = \frac{\sin^2(\theta) \left(\left(15\sqrt{3} - 26\right)\cos^2(\theta) + \sqrt{3} - 2 \right)}{3 \left(4\sqrt{3} - 7 \right)\cos(2\theta) + 8\sqrt{3} - 15}, \qquad \bar{k} = -\sqrt{3},$$
(86)

where the bar has been introduced to avoid possible confusions between the parameter k with the central extension k. Here, we have chosen our units such that the cosmological constant $\Lambda = 3/\ell^2$, with ℓ being the dS radius. The sign of \bar{k} is arbitrary and can be changed by sending $t \rightarrow -t$. We change to Eddington-Finkelstein-like coordinates

$$u = t - r, \quad \phi = \bar{\varphi} - \frac{\bar{k}r^2}{2},$$
 (87)

329 yielding

$$\frac{ds^2}{\ell^2} = \Gamma(\theta)(-du^2 - 2dudr + \alpha(\theta)d\theta^2) + \gamma(\theta)(d\bar{\varphi} + \bar{k}rdu)^2.$$
(88)

330 Upon setting

$$\bar{\varphi} = \bar{k}\varphi, \qquad \gamma(\theta) = \frac{\bar{\gamma}(\theta)}{\bar{k}^2},$$
(89)

331 we get

$$\frac{ds^2}{\ell^2} = \Gamma(\theta)(-du^2 - 2dudr + \alpha(\theta)d\theta^2) + \bar{\gamma}(\theta)(d\varphi + rdu)^2.$$
(90)

³³² Inspired by [99], we consider the following family of metrics

$$\frac{ds^2}{\ell^2} = \Gamma(\theta) \Big(2 \Big(P(u)r + T(u) \Big) du^2 - 2dudr + \alpha(\theta) d\theta^2 \Big) + \bar{\gamma}(\theta) (d\varphi + rdu)^2 \,, \tag{91}$$

where P and T are arbitrary functions of u. This family can be obtained by applying the finite coordinate transformation

$$u \to \mathcal{F}(u), \quad r \to \frac{1}{\mathcal{F}'}(r + \mathcal{G}'(u)), \quad \varphi \to \varphi - \mathcal{G}(u)$$
 (92)

to (90). The functions P, T, \mathcal{F} and \mathcal{G} are related by

. .

$$T(u) = -\frac{1}{2}\mathcal{F}'(u)^2 - \mathcal{G}''(u) + \frac{\mathcal{G}'(u)\mathcal{F}''(u)}{\mathcal{F}'(u)}, \quad P(u) = \frac{\mathcal{F}''(u)}{\mathcal{F}'(u)}.$$
(93)

336 4.2 Asymptotic Killing Vectors

³³⁷ The asymptotic Killing vectors generating the transformations (92) read

$$\xi = \epsilon(u)\partial_u - (r\epsilon'(u) + \zeta'(u))\partial_r + \zeta(u)\partial_\varphi, \qquad (94)$$

where $\epsilon(u)$ and $\zeta(u)$ are two arbitrary functions of u. We take the retarded time u to be periodic with period L, and define the generators

$$l_n = \xi(\epsilon = \frac{L}{2\pi} e^{2\pi i n u/L}, \zeta = 0), \quad j_n = \xi(\epsilon = 0, \zeta = \frac{L}{2\pi i} e^{2\pi i n u/L}),$$
(95)

which obey (17). By applying the Lie derivative on the metric (91), we find the variations of T(u) and P(u)

$$\delta_{\xi}T(u) = \left(2T(u)\epsilon'(u) + \epsilon(u)T'(u) - P(u)\zeta'(u) + \zeta''(u)\right),\tag{96a}$$

$$\delta_{\xi} P(u) = \Big(P(u)\epsilon'(u) + \epsilon(u)P'(u) + \epsilon''(u) \Big).$$
(96b)

342 4.3 Charge Algebra

³⁴³ We compute the surface charges from (18), yielding

$$Q = \frac{\ell^2}{8\pi G} \int_0^L du(\sqrt{3} - 1)(\epsilon(u)T(u) - \zeta(u)P(u)),$$
(97)

where we have integrated over a constant r, φ surface and taken the limit $r \to \infty$. Defining

$$L_n = Q_{l_n} = \frac{L\ell^2}{16\pi^2 G} \int_0^L du(\sqrt{3} - 1)e^{2\pi i n u/L} T(u), \qquad (98a)$$

$$J_n = Q_{j_n} = -\frac{L\ell^2}{16\pi^2 iG} \int_0^L du(\sqrt{3} - 1)e^{2\pi i nu/L} P(u), \qquad (98b)$$

one readily computes that the charges L_n , J_n obey (26) with c = k = 0 and

$$\kappa = \frac{1}{i} \frac{L\ell^2}{8\pi G} \left(\sqrt{3} - 1\right). \tag{99}$$

346 Acknowledgements

The authors thank Dionysios Anninos, Alejandra Castro, Daniel Grumiller, Tom Hartman, and 347 Chiara Toldo for useful discussions and exchanges on the topics covered in this work. We 348 thank Katharina Schäfer for initial collaboration on Sect. 4 of this paper.
