Abstract

Magnetic properties of CrO_2 are studied within the density functional theory plus dynamical mean-field theory (DFT+DMFT) approach in the paramagnetic phase. While the magnon dispersion in the 3-orbital model, containing only t_{2g} states, possesses negative branches in accordance with previous studies in ferromagnetic phase, this drawback is removed in the 5-orbital model, including all d -states. The model including oxygen states (with purely local interaction at chromium sites) overestimates the exchange interactions and spin wave stiffness, pointing to important contributions of double exchange in CrO_2 .

1 Introduction

Half metals represent an important class of magnetic materials, see, e.g., the review [1]. Having gapped minority spin band at the Fermi level in the ferromagnetic state, these systems can possess large magnetic moment, which finds its industrial applications. The properties of these systems are expected to be somewhat different from the strong magnets with both, minority and majority states present at the Fermi level. In the latter case large magnetic moment originates from the electron localization induced by Hund exchange [2–4] and exchange interaction is of RKKY type [5–7].

The prominent example of half metals with large magnetic moment is CrO_2 , which has Curie temperature $T_C \simeq 390$ K and saturation magnetic moment $\mu_s \simeq 2\mu_B$ per formula unit [8, 9]. The magnetic susceptibility shows the Curie-Weiss law with the square of magnetic moment $\mu_{\text{CW}}^2 = (8.3 \pm 0.3)\mu_B^2$ determined from the slope of inverse susceptibility [8, 10], which also corresponds to the effective spin $S_{\text{eff}} \simeq 1$, in agreement with the above mentioned saturation magnetic moment. These features can be considered as an indication of strong magnetism with well formed local magnetic moments.

Near the Curie temperature, when the Stoner splitting is small, strong magnetic half metals are expected to reveal closer similarity to the other strong magnets. The important question is therefore whether magnetic properties of these systems originate from the presence of local magnetic moments, and whether they strongly change between the low-temperature limit and

20 in the proximity of Curie temperature. The related problem is whether the effects of interaction
21 in such strong half metal magnets are more important than peculiarities of band structure yield-
22 ing half metallicity. Several experimental observations (photoemission, soft-x-ray absorption
23 and resistivity) show importance of correlation effects in CrO_2 [11–14]. Moderate correlation
24 effects were also observed in the angle-resolved photoemission (ARPES) experiments [15].
25 The conclusions of the latter study are also supported by bulk-sensitive photoemission data,
26 reported in Ref. [15], unveiling the occupied band structure of CrO_2 in the magnetic phase.

27 On the theoretical side, the density functional theory (DFT) calculations of CrO_2 [9, 16–18]
28 revealed splitting of the d states into the low lying t_{2g} states, which cross the Fermi level, and
29 hybridized with the oxygen states, and the e_g states, pushed above the Fermi level. In turn,
30 the t_{2g} states are split into the lower xy state and $yz \pm xz$ excited states (the notation of
31 the states refer to the local coordinate frame). The dispersion of the xy states is almost flat,
32 which promotes the interaction effects. In particular, the localization of the xy states by the
33 interaction effects was suggested in Ref. [19]. The importance of correlation effects was also
34 emphasized in the subsequent L(S)DA+DMFT studies [15, 20–23].

35 In accordance with the localization of the xy t_{2g} states and more itinerant nature of the
36 $yz+xz$ states the double exchange nature of magnetic exchange was proposed in Refs. [19, 24].
37 Yet, recent experimental studies did not find mixed valence of chromium atoms [25, 26], in
38 contrast to the previous results [27]. The exchange interactions in CrO_2 were studied using
39 the DFT [28, 29], Hartree-Fock [29–31], and the combination of DFT with the dynamical mean
40 field theory (DFT+DMFT) approach [29], which produce diverse values of exchange interac-
41 tions. Application of the DFT+DMFT approach to the effective 3-orbital model, containing t_{2g}
42 states only, produced negative branches of the magnon dispersion, pointing to the instability of
43 ferromagnetism in that model [29]. The authors of Ref. [29] suggested inclusion of the oxygen
44 states to stabilize the ferromagnetism. Therefore, despite long history of studying CrO_2 , there
45 is no common view on the mechanism of magnetic exchange and the magnitude of exchange
46 interactions in this material.

47 Recently, the DFT+DMFT approach to treat the exchange interactions in the paramagnetic
48 state was proposed [32]. This approach provides a possibility to study exchange interactions
49 without imposing certain magnetic order, which allows one to obtain an unbiased information
50 about these interactions. For strong half metals, like CrO_2 this may also help to emphasize the
51 effect of correlations, especially near Curie temperature, where the corresponding magnetic
52 splitting of the states is small.

53 In the present paper we revisit the problem of magnetism of CrO_2 within the DFT+DMFT
54 approach. We show that in agreement with the earlier considerations the xy t_{2g} states appear
55 to be more localized. We furthermore apply the recently proposed technique of calculation
56 of exchange interactions in paramagnetic phase within the DFT+DMFT approach [32]. Using
57 the obtained exchange interactions, we also obtain magnon dispersions and show that they
58 are qualitatively and semi-quantitatively similar to those obtained in the ferromagnetic state.
59 Remarkably, the magnon dispersion in the 5-orbital model (per chromium site) is positively
60 definite, providing stability of ferromagnetism due to the e_g states.

61 Therefore, on the basis of these results, we show that magnetic properties of half metals can
62 be well described starting from the paramagnetic phase, showing the correspondence of the
63 properties of the symmetric and symmetry broken phases of these systems. Among considered
64 models, we find that the low energy 5-orbital model (per Cr site), is quantitatively sufficient
65 to describe ferromagnetism of CrO_2 . We argue that 11-orbital model (per Cr site) requires
66 considering effects of the non-local Coulomb interaction.

2 Methods

2.1 DFT

The CrO_2 has $P4_2/mnm$ space group (point symmetry group D_{4h}). The DFT calculations were performed using the pseudo-potential method implemented in the Quantum Espresso [33] package supplemented by the maximally localized Wannier projection onto $3d$ states of Cr performed within Wannier90 package [34], which produces the resulting tight-binding 5-orbital model (here and in the following we specify the number of the orbitals per Cr site, the actual number of orbitals in the respective models is doubled because of the two sites in the unit cell). For comparison, we also considered the tight-binding Hamiltonian, which includes the p oxygen states, resulting in the 11-orbital model per Cr site. We use the lattice parameters $a = 4.422\text{\AA}$, $c = 2.916\text{\AA}$ [29, 35]. The reciprocal space integration was performed using $16 \times 16 \times 16$ \mathbf{k} -point grid.

The resulting band structure and the density of states are shown in Fig. 1. The e_g (t_{2g}) states can be constructed in the 5-orbital model by choosing the symmetric (antisymmetric) combination of d_{xy} and $d_{3z^2-r^2}$ states, as well as d_{xz} and d_{yz} states in the global reference frame (we perform the transformation $d_{yz} \rightarrow -d_{yz}$ and $d_{xy} \rightarrow -d_{xy}$ on one of the two chromium sites); the third t_{2g} state is identified with the $d_{x^2-y^2}$ state in the global reference frame, see Ref. [29]. We choose the rotation angles between the above mentioned states to diagonalize the crystal field; the obtained angle θ_1 of mixing of d_{xy} and $d_{3z^2-r^2}$ states is close to $\pi/6$ and for another pair of states it is equal to $\pi/4$. We note that Wannier functions of the d states in the 5-orbital model contain also an admixture of the oxygen states near the Fermi level (see Appendix A), while in 11 orbital model the hybridization is accounted via the hopping parameters. To construct the model with 3 orbitals per Cr site, corresponding to considering only t_{2g} states, we project out the resulting e_g states in the 5-orbital model as $H_{\text{eff}} = H_{t_{2g}} + H_{t_{2g},e_g} [\mu_{\text{DFT}} - H_{e_g}]^{-1} H_{e_g,t_{2g}}$, where μ_{DFT} is the DFT chemical potential and H_i and H_{ij} ($i, j = e_g, t_{2g}$) are the respective diagonal and off-diagonal blocks of the tight-binding Hamiltonian. We have verified, that the resulting Hamiltonian reproduces correctly the dispersion of the t_{2g} states close to the Fermi level, see Fig. 1.

2.2 DMFT

In DMFT calculations we consider the density-density interaction matrix, see the details in Ref. [32]. For the 5-orbital and 11-orbital models we have parameterized the interaction at the Cr sites by Slater parameters $F^0 = 1.99$ eV, $F^2 = 7.67$ eV, and $F^4 = 5.48$ eV, as obtained in Ref. [31]. For the 3-orbital model we use the Kanamori parameterization with the interactions $U_K = 2.84$ eV and $J_K = 0.70$ eV, obtained in Refs. [29, 31]. The corresponding Slater parameters (see, e.g., Supplementary Material of Ref. [36]) $U_S = 1.91$ eV, $J_S = 1.17$ eV. The parameter U_S is smaller than the corresponding parameter $U_S = F^0$ of the 5-orbital model due to screening of the interaction. For 11-orbital model we use a double-counting correction $H_{\text{DC}} = M_{\text{DC}} \sum_{ir} n_{ird}$ in the around mean-field form [37],

$$M_{\text{DC}} = \langle n_{ird} \rangle [U_S(2n_{\text{orb}} - 1) - J_S(n_{\text{orb}} - 1)] / (2n_{\text{orb}}), \quad (1)$$

where n_{ird} is the operator of the number of d electrons at the site (i, r) , i is the unit cell index and r is the site index within the unit cell, n_{orb} is the number of considered orbitals per site, $J_S = (F^2 + F^4)/14$. We have verified that the fully localized form of the double counting produces quite close results.

Figure 1: Left plot: band structure (dashed lines) and its wannierization (solid lines) in 5-orbital model (per Cr site, including only d states, blue lines) and 11-orbital (per Cr site, including d states of chromium and p states of oxygen, red and blue lines) models. The green circles show the band structure of the reduced t_{2g} states model (3 orbitals per Cr site, see text). Right plot shows the respective density of states.

109 2.3 Treatment of the d - p interaction

110 Apart from the standard Coulomb repulsion in the chromium d -shell, parameterized by Slater
 111 parameters, we consider also a model including the d - p chromium-oxygen interaction U_{dp} , as
 112 well as the repulsion between oxygen p -states, parameterized by Kanamori parameters U_{pp} ,
 113 U'_{pp} , and J_{pp} , with the Hamiltonian

$$H_{dp} = U_{dp} \sum_{\langle ij \rangle} n_i n_j + U_{pp} \sum_{j,m} n_{jm\uparrow} n_{jm\downarrow} + \frac{U'_{pp} - J_{pp}}{2} \sum_{j,m \neq m',\sigma} n_{jm\sigma} n_{jm'\sigma} + \frac{U'_{pp}}{2} \sum_{j,m \neq m',\sigma} n_{jm\sigma} n_{jm',-\sigma}, \quad (2)$$

114 where i numerates chromium sites, j numerates oxygen sites, $\langle ij \rangle$ denotes nearest neighbours,
 115 $n_i = \sum_{m\sigma} n_{im\sigma}$, and $n_{im\sigma} = c_{im\sigma}^\dagger c_{im\sigma}$. We treat these interactions within the static mean field
 116 approximation, assuming approximately equal occupations of oxygen p -orbitals, characterized
 117 by total occupation $\langle n_O \rangle$ per oxygen atom,

$$H_{dp}^{\text{MF}} = [U_{dp} z_O \langle n_{\text{Cr}} \rangle + \tilde{U}_{pp} \langle n_O \rangle] \sum_j n_j + U_{dp} z_{\text{Cr}} \langle n_O \rangle \sum_i n_i, \quad (3)$$

118 where $\tilde{U}_{pp} = U_{pp}/(2n_p) + (U'_{pp} - J_{pp}/2)(1 - 1/n_p)$, $n_p = 3$ is the number of p -orbitals, $z_{\text{Cr}} = 6$,
 119 $z_O = 3$ are the coordination (nearest neighbour) numbers of chromium and oxygen sites, $\langle n_{\text{Cr}} \rangle$
 120 is the respective chromium occupation of Cr per atom. Following Ref. [38], we subtract the
 121 double counting contribution, which is equal to the oxygen and chromium energy shifts in Eq.
 122 (3) with the DFT occupations $\langle n_{\text{Cr}} \rangle_0$ and $\langle n_O \rangle_0$. The resulting energy shifts of the chromium
 123 and oxygen states are given by

$$\begin{aligned} \Delta E_{\text{Cr}} &= U_{dp} z_{\text{Cr}} [\langle n_O \rangle - \langle n_O \rangle_0] = -U_{dp} z_{\text{Cr}} [\langle n_{\text{Cr}} \rangle - \langle n_{\text{Cr}} \rangle_0] / r, \\ \Delta E_O &= U_{dp} z_O [\langle n_{\text{Cr}} \rangle - \langle n_{\text{Cr}} \rangle_0] + \tilde{U}_{pp} [\langle n_O \rangle - \langle n_O \rangle_0] = (U_{dp} z_O - \tilde{U}_{pp} / r) [\langle n_{\text{Cr}} \rangle - \langle n_{\text{Cr}} \rangle_0], \end{aligned} \quad (4)$$

124 where $r = 2$ is the ratio of oxygen and chromium sites in the formula unit, and we have
 125 taken into account that the total number of electrons $\langle n_{\text{Cr}} \rangle + r\langle n_{\text{O}} \rangle = \langle n_{\text{Cr}} \rangle_0 + r\langle n_{\text{O}} \rangle_0$ is con-
 126 served. Finally, absorbing the shift $\Delta E'_{\text{Cr}}$ at the chromium sites into the chemical potential
 127 $\mu \rightarrow \mu + U_{dp} z_{\text{Cr}} [\langle n_{\text{Cr}} \rangle - \langle n_{\text{Cr}} \rangle_0] / r$, we find the energy shift of oxygen p -states

$$\Delta E'_O = (z_O + z_{\text{Cr}}/r) \tilde{U}_{dp} [\langle n_{\text{Cr}} \rangle - \langle n_{\text{Cr}} \rangle_0] \quad (5)$$

128 where $\tilde{U}_{dp} = U_{dp} - \tilde{U}_{pp}/(rz_O + z_{\text{Cr}})$. In DMFT calculation we account for this energy shift
 129 as (taken with the opposite sign) double counting correction of the oxygen p -states. The
 130 parameter \tilde{U}_{dp} controls the energy shift of oxygen states. For calculations we consider the
 131 parameters $U_{pp} = 1.5\text{eV}$, $J_{pp} = 0.5\text{eV}$, $U_{dp} = 0.65\text{eV}$, $U'_{pp} = U_{pp} - 2J_{pp}$, which yield $\tilde{U}_{dp} \simeq 0.6\text{eV}$.
 132 Since the screening of d - d interaction by p states is beyond the Hartree-Fock approximation,
 133 we use the same parameters of the local interaction within d -shell, as for the 5-orbital model.

134 2.4 Exchange interactions

135 To determine the exchange interactions we consider the effective Heisenberg model with the
 136 Hamiltonian $H = -(1/2) \sum_{\mathbf{q}, rr'} J_{\mathbf{q}}^{rr'} \mathbf{S}_{\mathbf{q}}^r \mathbf{S}_{-\mathbf{q}}^{r'}$, $\mathbf{S}_{\mathbf{q}}^r$ is the Fourier transform of static operators \mathbf{S}_{ir} ,
 137 where the orbital-summed on-site static spin operators $\mathbf{S}_{ir} = \sum_m \mathbf{S}_{irm}$ and

$$\mathbf{S}_{irm} = \frac{1}{2} \sum_{\sigma\sigma'\nu} c_{irm\sigma\nu}^+ \boldsymbol{\sigma}_{\sigma\sigma'} c_{irm\sigma'\nu} \quad (6)$$

138 is the electron spin operator, ν are the Matsubara frequencies, $c_{irm\sigma\nu}^+$ and $c_{irm\sigma\nu}$ are the fre-
 139 quency components of the electron creation and destruction operators at the site (i, r) , d -
 140 orbital m , and spin projection σ , and $\boldsymbol{\sigma}_{\sigma\sigma'}$ are the Pauli matrices.

141 We relate exchange parameters $J_{\mathbf{q}}$ to the orbital-summed non-local static longitudinal sus-
 142 ceptibility $\chi_{\mathbf{q}}^{rr'} = -\langle\langle S_{\mathbf{q}}^{z,r} | S_{-\mathbf{q}}^{z,r'} \rangle\rangle_{\omega=0} = \sum_{mm'} \hat{\chi}_{\mathbf{q}}^{mr,m'r'}$ (the hats stand for matrices with respect
 143 to orbital and site indexes; $\langle\langle \dots \rangle\rangle_{\omega}$ is the retarded Green's function), by (see Refs. [32, 39, 40])
 144 $J_{\mathbf{q}} = \chi_{\text{loc}}^{-1} - \chi_{\mathbf{q}}^{-1}$, the matrix inverse is taken with respect to the site indexes in the unit cell. The
 145 matrix of local susceptibilities $\chi_{\text{loc}}^{rr'} = -\langle\langle S_{ir}^z | S_{ir}^z \rangle\rangle_{\omega=0} \delta_{rr'} = \sum_{mm'} \hat{\chi}_{\text{loc}}^{mm',r} \delta_{rr'}$ is diagonal with
 146 respect to the site indexes. The non-local susceptibility is determined from the Bethe-Salpeter
 147 equation using the local particle-hole irreducible vertices [41], accounting also the corrections
 148 for the finite frequency box (cf. Refs. [32, 42]). The local irreducible vertices are extracted
 149 from the inverse Bethe-Salpeter equation applied to the local particle-hole vertex obtained
 150 within the DMFT [41].

151 The DMFT calculations of the self-energies, non-uniform susceptibilities and exchange in-
 152 teractions were performed using the continuous time Quantum Monte Carlo method of the
 153 solution of impurity problem [43], realized in the iQIST software [44], see also Refs. [32, 39].

154 3 Results

155 In Fig. 2(a) we show the partial densities of states for $\beta = 10 \text{eV}^{-1}$, compared to those in DFT
 156 approach. The occupation of Cr sites is fixed to 2 electrons per site in 3- and 5-orbital models,
 157 corresponding to fixed valence of Cr sites. The respective hybridized low energy oxygen and
 158 chromium states, forming Wannier functions, are considered as interacting ones. At the same
 159 time, in 11-orbital model the occupation is determined by the total filling of 28 electrons
 160 per unit cell, and constitutes 3.75 per Cr site (see fillings of the d orbitals in Table 1 and
 161 density-density correlators in Appendix B). The increase of the filling originates from strong

	$n(l_{xy})$	$n(l_{xz-yz})$	$n(l_{xz+yz})$	$n(l_{3z^2-r^2})$	$n(l_{x^2-y^2})$	n_d
3-orb	0.49	0.34	0.17	0	0	2
5-orb	0.47	0.36	0.14	0.02	0.01	2
11-orb	0.52	0.45	0.39	0.27	0.26	3.75
11-orb + $U_{dp,pp}$	0.48	0.40	0.25	0.16	0.15	2.87

Table 1: Fillings $n(l)$ of d -orbitals l_α per one spin projection and the total filling of d -states n_d in DFT+DMFT approach. The notation of the orbitals refer to the local coordinate frame; the fillings are estimated at $\beta = 10 \text{ eV}^{-1}$, but only weakly depend on temperature.

162 hybridization of chromium and oxygen states, as discussed earlier in DFT approaches [9, 16–
163 19, 24].

164 In Figs. 2(b,c) we show the frequency dependence of the electronic self-energies. In agree-
165 ment with previous considerations, the two of the three t_{2g} states $l_{xy} = \cos \theta_1 d_{3z^2-r^2} - \sin \theta_1 d_{xy}$
166 and $l_{xz-yz} = (d_{xz} - d_{yz})/\sqrt{2}$ (the indexes of l_i refer to the local reference frame according to
167 Refs. [18, 19, 29]) appear to have larger damping, and, respectively, more localized. On the
168 other hand, the t_{2g} state $l_{xz+yz} = d_{x^2-y^2}$, as well as e_g states have smaller damping, and ap-
169 pear to be more itinerant. Closer proximity of the t_{2g} states l_{xy} and l_{xz-yz} to half filling in
170 the 11-orbital model provides enhancement of correlations (cf. Ref. [45]), in particular non-
171 quasiparticle form of the self-energy of these states with $\partial \text{Im}\Sigma(i\nu)/\partial \nu = \partial \text{Re}\Sigma(\nu)/\partial \nu > 0$ at
172 small frequencies, which yields larger local magnetic moments (see below).

173 To treat properly hybridization of d and p states, we additionally consider the 11-orbital
174 model, including repulsion U_{pp} between oxygen p states, as well as non-local interaction U_{dp}
175 between chromium d and oxygen p states within the static mean-field approximation, together
176 with DMFT for the chromium d states (see Sect. 2.3). The respective fillings (see Table 1) in
177 the presence of these additional interactions become closer to the 5-orbital model; the filling of
178 chromium d states constitutes in this case 2.87 electrons. The results for the spectral function
179 and self-energy of the 11-orbital model with included interactions U_{pp} and U_{dp} are shown in
180 Fig. 3. One can see that the shift of p -states leads to suppression of $d-p$ hybridization, such
181 that both, the spectral functions and self-energy become close to those in 5-orbital model.

182 One can also see that, in agreement with the earlier studies [23], in all considered models
183 the peak of the density of states, which is present in DFT approach at the Fermi level, is pushed
184 to the energy $\nu_{\text{peak}} \sim -0.5 \text{ eV}$ in DFT+DMFT approach. We have verified that the l_{xy} state
185 in the considered 5- and 11-orbital models provides largest contribution to the peak of the
186 density of states close to the Fermi energy, which shift can be therefore identified with the large
187 quasiparticle damping of the corresponding states. This shift is therefore similar to the earlier
188 discussed in two-dimensional systems gap formation in the vicinity of the antiferromagnetic
189 state [46] and the Fermi surface quasi-splitting near the ferromagnetic instability [47, 48],
190 although in the present case large damping occurs due to electronic, rather than magnetic
191 correlations, which implies (similarly to the antiferromagnetic state) that it does not depend
192 on the momentum (being almost local in real space).

193 The temperature dependence of the inverse uniform $\chi_{q=0} = \chi_{q=0}^{11} + \chi_{q=0}^{12}$ and local

$$\chi_{\text{loc}} = -\langle\langle S_{ir}^z | S_{ir}^z \rangle\rangle_{\omega=0} = \sum_{mm'} \hat{\chi}_{\text{loc}}^{mm',r} \quad (7)$$

194 susceptibilities in the 3- and 5-orbital models, as well as 11-orbital models, is almost linear, as
195 shown in Fig. 4, which points to the existence of well formed local magnetic moments. The
196 Curie temperatures, obtained from vanishing of inverse uniform susceptibility are presented

197 in Table 2. Due to the mean-field nature the dynamical mean-field theory approach is known to
 198 overestimate Curie temperature. Therefore, obtained Curie temperatures can be considered
 199 as an upper bound and corrected below with account of the non-local correlations.

200 From the slope of inverse local and uniform magnetic susceptibilities we extract the local
 201 magnetic moments μ_{loc}^2 and μ^2 according to

$$\chi_{\text{loc}}^{-1} = 3(g\mu_B)^2(T + T_W)/\mu_{\text{loc}}^2, \quad (8)$$

$$\chi_{\text{q}=0}^{-1} = 3(g\mu_B)^2(T - T_C)/\mu^2 \quad (9)$$

202 where $g = 2$ (see Table 2). In terms of the effective spin, defined by $g^2 S_{\text{eff}}(S_{\text{eff}} + 1) = \mu_{\text{loc}}^2$,
 203 this corresponds to $S_{\text{eff}} = 1.2$ for three- and five-orbital models and $S_{\text{eff}} = 1.27$ for the 11-
 204 orbital models. We note that the magnetic moments, especially extracted from local magnetic
 205 susceptibility, are somewhat overestimated in the considered density-density approximation,
 206 which neglects transverse components of Hund exchange, see Refs. [36, 49]. From the uni-
 207 form susceptibility we obtain somewhat smaller magnetic moments, which are in a reasonable
 208 agreement with the experimental data ($\mu^2/\mu_B^2 = 8.3 \pm 0.3$, Refs. [8, 10]). The Weiss tem-
 209 perature T_W of the inverse local magnetic susceptibility appears to be quite small, showing
 210 smallness of the Kondo temperature [50, 51].

Table 2: Magnetic moments and Curie temperatures in DFT+DMFT approach. The notation of the orbitals refer to the local coordinate frame.

211 Using the approach of Refs. [32, 39, 40] we obtain the exchange interactions $J_{\mathbf{q}}^{rr'}$. We note
 212 that having smaller bandwidth, and fully filled oxygen p states well below the Fermi level,
 213 the 5-orbital model describes magnetic exchange mechanism similar to the double exchange
 214 type. At the same time, uncorrelated oxygen states in 11-orbital model mediate magnetic
 215 exchange of RKKY type. The Fourier transformation of the obtained exchange interactions at
 216 $\beta = 10 \text{ eV}^{-1}$ is presented in Table 3. The obtained exchange interactions are comparable to
 217 those obtained in the ferromagnetic state in Refs. [29, 31], with the exchange interactions be-
 218 tween the nearest neighbour sites larger in the presence of the oxygen states, than in the 3- and
 219 5-orbital models, due to larger hybridization of chromium states. With including U_{dp} and U_{pp}

N_{orb}	J_1	J_2	J_3	J_4	J_5	J_6	$J_7^>$	$J_7^<$	$J_8^>$	$J_8^<$

11-orb+ $U_{dp,pp}$	8.8	18.0	-0.1	0.1	-0.4	-0.6	-2.9	-0.7	-0.7	-1.1

Table 3: Exchange interactions (in meV) between various chromium sites at $\beta = 10 \text{ eV}^{-1}$ for the 3- and 5 orbital models per chromium site, as well as 11-orbital models, including oxygen states. 11 dp stands for the model with U_{dp} , U_{pp} interactions. The notation of the exchange interactions is the same as in Refs. [29, 31].

220 interactions, the nearest neighbour exchange is suppressed in 11-orbital model; the antiferromagnetic exchanges at longer distances are however also suppressed, reducing frustration effects.

223 Using the obtained exchange interactions in the temperature range $T \gtrsim T_C$, we obtain
 224 magnon dispersion as the \mathbf{q} -dependent eigenvalues of the matrix of the spin-wave Hamiltonian
 225 (cf. Refs. [39, 40]), assuming that the exchange interactions do not change strongly with
 226 lowering the temperature. The resulting magnon dispersions are shown in Fig. 5. One can
 227 see that the magnon dispersion of the 3-orbital model possesses negative branches, showing an
 228 instability of ferromagnetism, similarly to previous study in the ferromagnetic phase [29]. At
 229 the same time, the magnon dispersions of the 5-orbital model are positive definite, providing
 230 the stability of the ferromagnetic state. Therefore, inclusion of the e_g states seems to be crucial
 231 for the stability of ferromagnetism. The maximal energy of the obtained magnon dispersion
 232 in the 5-orbital model is larger than that in the “method \hat{b} ” of Ref. [31], corresponding to
 233 the infinitesimal rotation of exchange-correlation potential, but comparable to that obtained
 234 in the “method \hat{m} ” of Ref. [31] (considering infinitesimal rotation of magnetization). The
 235 dispersion in the model including oxygen states without additional U_{dp} and U_{pp} interactions is
 236 somewhat larger than in the 5-orbital model due to larger exchange interactions, but becomes
 237 comparable to that for the 5-orbital model with account of $U_{dp,pp}$ interactions.

238 The temperature dependencies of the obtained spin-wave stiffnesses in the 5-orbital model
 239 in various directions are shown in Fig. 6. One can see that the average spin-wave stiffness, ex-
 240 trapolated to the low-temperature limit, $D_{av} \simeq 110 \text{ meV}\cdot\text{\AA}^2$ is in a reasonable agreement with
 241 the experimental data $D = 60$ to $150 \text{ meV}\cdot\text{\AA}^2$, Refs. [52–54]. At the same time, the 11-orbital
 242 models yield larger value of the spin-wave stiffness, $D_{av} \gtrsim 200 \text{ meV}\cdot\text{\AA}^2$ (not shown). Although
 243 the interactions $U_{dp,pp}$ yield the suppression of exchange interactions and the spin wave stiff-
 244 ness D_z in 11-orbital model, spin wave stiffness D_{xy} is increased by these interactions due to
 245 suppression of antiferromagnetic exchange interactions $J_{7,8}$ (the suppressed ferromagnetic in-
 246 teraction J_1 acts along the z axis and therefore contributes to D_z only). This may show, that for
 247 accurate description of the low-energy magnon dispersion in 11-orbital model the treatment
 248 of the non-local interaction beyond simplest static mean field approximation is required.

249 Finally, to estimate the non-local corrections to the Curie temperature beyond DMFT, we
 250 use the RPA approach [55], see also Ref. [39]. Assuming that the sites of the unit cell are
 251 equivalent, we find

$$T_C = \frac{\mu^2}{3(g\mu_B)^2 \sum_{\mathbf{q}} [\lambda \delta_{rr'} - J_{\mathbf{q}}^{rr'}]_{11}^{-1}}, \quad (10)$$

252 where $\lambda = \sum_{r'} J_0^{rr'}$. The obtained results taking the obtained exchange interactions at $\beta = 10 \text{ eV}^{-1}$
 253 are presented in Table 2. With account of the non-local corrections, the Curie temperature is
 254 suppressed with respect to the DMFT Curie temperature, and for the 5-orbital model only
 255 moderately overestimates experimental data. For the 11-orbital models the Curie temperature
 256 is stronger overestimated; for the model including $U_{dp,pp}$ interactions the suppression of Curie
 257 temperature with respect to DMFT appears not too strong because of weakened frustration
 258 effects in this model.

259 The success of the 5-orbital model in description of the magnetic properties of CrO_2 relies
 260 on the fact that this model is better suited to describe double exchange interaction, having also
 261 lower band width, comparable to Hund exchange interaction. Describing the double exchange
 262 interaction within 11-orbital model requires accurate (possibly, non-perturbative) treatment
 263 of the non-local Coulomb interactions.

264 4 Conclusion

265 In summary, we have evaluated non-uniform susceptibilities, Curie temperatures, and ex-
266 change interactions in 3-, 5-, and 11-orbital (per Cr site) models within DFT+DMFT approach.
267 The most reasonable results are obtained within the low-energy 5-orbital model, representing
268 double exchange interaction. This model yields positive magnon dispersions and reasonable
269 Curie temperature, although the latter is still overestimated with respect to the experimental
270 data. The overestimate of the Curie temperature is likely connected with the assumed density-
271 density form of the Coulomb interaction (cf. Ref. [36]), presence of magnetic frustrations, etc.
272 We show also that the considered approach allows for a correct description of the experimental
273 data for the spin-wave stiffness.

274 At the same time, the 11-orbital model, including oxygen states, yields strong hybridiza-
275 tion of these states with chromium states at the energies well below the Fermi level, which
276 results in the filling of d-orbitals of Cr closer to half filling, and therefore stronger correlations.
277 Remarkably, we find RKKY mechanism of magnetic exchange, represented by 11-orbital model
278 with local Coulomb interaction, inapplicable even in paramagnetic phase of CrO_2 . We argue
279 that considering non-local interaction between chromium and oxygen sites (together with U_{pp}
280 interaction) within static mean field approximation increases occupation of oxygen p states
281 and substantially improves the results for the 11-orbital model. At the same time, it yields
282 larger spin-wave stiffness, than that for 5-orbital model and experimental data. Likely, treat-
283 ment of non-local interactions beyond static mean-field approximation, e.g. within cluster
284 methods or non-local extensions of dynamical mean-field theory [41, 42, 56–58], will further
285 improve the results of this model.

286 The possibility of describing reasonably well magnetic properties of CrO_2 from the para-
287 magnetic phase implies presence of the correspondence between the magnetic properties in
288 ferro- and paramagnetic phases. Mathematically, this correspondence occurs due to compen-
289 sation of the self-energy and vertex corrections to the spin susceptibility, which was discussed
290 earlier in the ferro- [59] and paramagnetic [32] phases. The performed study also implies
291 formation of local magnetic moments in CrO_2 due to Hund exchange interaction, and their
292 double exchange-like interaction even in paramagnetic phase.

293 Further experimental and theoretical studies of the form of magnon dispersion, and its
294 evolution from the low- to the high-temperature limit are of certain interest. Also describing
295 the effect of the non-local chromium-oxygen interaction, as well as the consideration of mag-
296 netic properties of CrO_2 with full $\text{SU}(2)$ symmetric Coulomb interaction has to be performed
297 in future.

298 Acknowledgements

299 The author appreciates stimulating discussions with I. V. Solovyev at the early stage of the
300 work. The calculations were performed on the cluster of the Laboratory of Material Computer
301 Design of MIPT and the Uran supercomputer at the IMM UB RAS.

302 The DMFT calculations are supported by the project of Russian Science Foundation 24-12-
303 00186. The DFT calculations are performed within the theme “Quant” 122021000038-7. of
304 the Ministry of Science and Higher Education of the Russian Federation.

305 A Wannier orbitals in 5- and 11-orbital models

306 In Figs. 7 and 8 we visualize [60] Wannier orbitals in 5- and 11-orbital models (before per-
 307 forming basis rotation which diagonalises crystal field). One can see that in the 5-orbital
 308 model Wannier functions contain substantial admixture of the oxygen states, originating from
 309 the bands the vicinity of the Fermi level, while in 11-orbital model Wannier functions are
 310 more localized at chromium and oxygen sites. As it is discussed in the main text in the latter
 311 model however the hybridization occurs via the hopping parameters, which in particular yield
 312 additional contribution to the density of d states at the energies well below the Fermi level
 313 ($\nu \sim -4$ eV).

314 B Density correlations in DFT+DMFT approach

315 In Tables 4, 5, and 6 we present the density-density correlation function $\langle n_{m\sigma} n_{m'\sigma'} \rangle$ in 5- and
 316 11-orbital models in DFT+DMFT approach at $\beta = 10$ eV $^{-1}$. In the 5-orbital model the density
 317 correlation matrix has only few off-diagonal elements, the major one is between l_{xy} and l_{xz-yz}
 318 orbitals in the local coordinate frame, which have largest quasiparticle damping (see Fig. 2
 319 of the main text). The 11-orbital model with local interaction possesses stronger off-diagonal
 320 correlations, which reflects stronger mixing of various orbital states in this model. On the
 321 other hand, in 11-orbital model with U_{dp} and U_{pp} interactions the correlations become more
 322 diagonal, and resemble the results for the 5-orbital model.

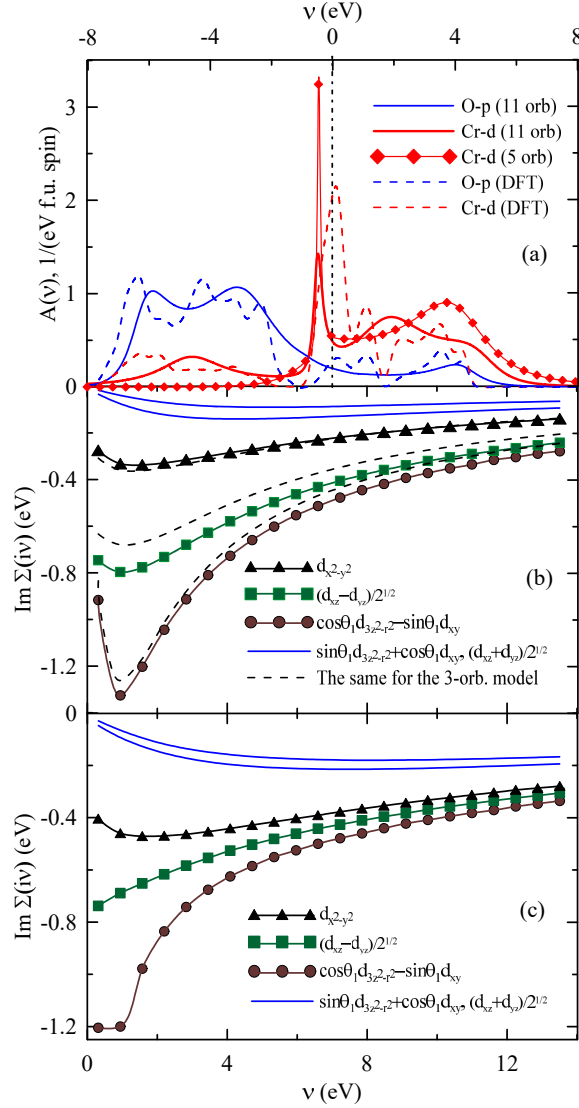

Figure 2: The DFT (dashed lines) and DFT+DMFT (solid lines) partial densities of states at the real frequencies (a) and the imaginary part of the self-energy at the imaginary frequency axis for states of different symmetry in five-orbital (solid lines), three-orbital (dashed lines) (b) and 11-orbital (c) model at $\beta = 10 \text{ eV}^{-1}$ in the DFT+DMFT approach with on-site Coulomb repulsion.

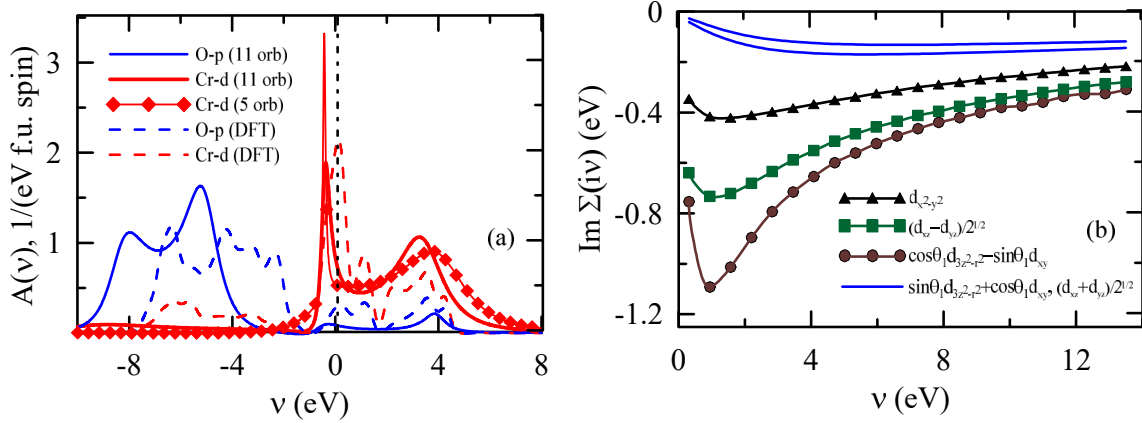

Figure 3: Spectral functions (a) and electronic self-energies (b) in the 11-orbital model with account of U_{pp} and non-local U_{dp} interactions

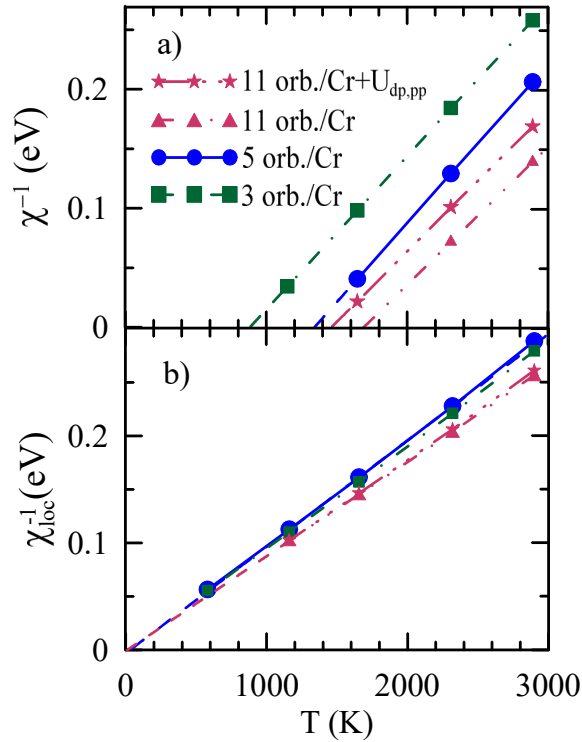

Figure 4: Temperature dependence of the inverse longitudinal uniform (a) and local (b) susceptibilities of CrO_2 within the DFT+DMFT approach. Solid blue lines correspond to the five-orbital model per Cr site, dot-dashed green lines correspond to the three-orbital model, red dot-dot-dashed (dot-dot-dot-dashed) lines to the 11 orbital model per Cr site, including oxygen states without (with) additional U_{dp} and U_{pp} interactions.

Figure 5: Magnon dispersion at $\beta = 7 \text{ eV}^{-1}$ (solid lines) and $\beta = 10 \text{ eV}^{-1}$ (dashed lines) (a) in the models with three (green lines with symbols) and five orbitals (blue lines) per Cr site and (b) in the models with 11 orbitals per Cr site which includes oxygen states, with (dark yellow lines) or without (red lines with symbols) additional U_{dp} and U_{pp} interactions.

Figure 6: Temperature dependencies of the obtained spin-wave stiffnesses in the x , y (red circles) and z (green squares) directions, together with the average spin-wave stiffness $D_{av} = (D_{xx}^2 D_{zz})^{1/3}$ (black stars) in the five-orbital model. Dashed lines show the result of extrapolation. The inset shows momentum dependencies of magnon energies at $\beta = 10 \text{ eV}^{-1}$ in the respective directions in logarithmic scale, dashed line corresponds to quadratic fit.

Figure 7: Visualization of Wannier orbitals in 5-orbital model (per Cr site), including only d states. Blue circles in the center (partly hidden by Wannier orbitals) correspond to chromium atom, red lines and circles show the bonds and oxygen atoms.

Figure 8: Visualization of Wannier orbitals in 11-orbital model (per Cr site) at chromium (a-e) and one of the oxygen (f-h) sites. The notations are the same as in Fig. 7.
